more important to the practitioner in recent years from the competition induced by the holders of degrees passing into general practice instead of remaining consultants, as was formerly the more usual custom. This is a direct consequence of the large increase in men who pass out from our various universities after having observed the necessary curricula and passed the required examinations. Formerly graduates were comparatively few, and those who held qualifying diplomas were an immense majority. Of late years this disproportion has undergone a great change, and now holders of university degrees can everywhere be found in the ranks of the general practitioner, and we hail this change as one of the surest proofs of a general rise in the social and educational status of our profession during the past twenty or thirty years. It must not be forgotten, however, that, coincidently with the development of the universities as centres of medical education, the corporations have also done much for its improvement, and have so greatly altered their requirements and strengthened their examinations that they no longer hold the position to the present which they did to the former generation of medical practitioners. By the formation of a Conjoint Examining Board in England for the two Royal Colleges, a plan has been evolved from the old chaos of medical education and medical examinations; and it is a matter of much interest to review the present position of the medical student in London, and to compare his advantages and disadvantages with those elsewhere. In the first place, there can be no question that his clinical opportunities—and these are the essentials for his future practical work—are far greater in the metropolis than in any other medical centre, and that in some of the smaller provincial cities, with large medical schools, his ward work and clinical instruction must dwindle to a minimum. Against this positive gain must be set the disadvantage of his having to choose between multiple schools, with teachers of varying capacity and eminence attached to each school, whilst distance prevents any choice of classes in different schools. Undeniably, university professors, especially when extra-mural teachers have free scope as rival teachers, teach better than many in our metropolitan schools, but then they are encumbered by large classes, and can give but little personal supervision or encouragement except to a select few of their *alumni*. A direct and personal form of teaching is so much required for practical and clinical work, that we hope our smaller metropolitan schools will in time transfer the theoretical and scientific education of our students to expert teachers in three or four centres, and devote themselves and their institutions to this final work, for which they are so remarkably fitted. If such a plan could be carried out, the medical education of the London student would be almost ideally perfect, and the recent changes with regard to teaching botany and chemistry, by the practical throwing open of the certificates in these subjects, must soon bring this reform into the domain of practical expediency. But even at present, it is only just that the London student should have the proper facilities for obtaining a medical degree, and so far as the stringency and thoroughness of the present medical examinations of the Conjoint Examining Board in England are concerned, nothing more is necessary or desirable. They are quite equal to most of those instituted by the universities, and are even superior to some in the efficiency of their practical tests. There is no feasible objection, except that of the multiplication of degree-giving bodies, which can be urged against the combined colleges forming the medical faculty of a university, and having a power to grant degrees in consequence, and this objection fails when we find now all universities examining students destined for general practice, and see how valuable is the influence of a new and living institution like the Victoria University. The University of London is cosmopolitan, and can only be an examining body for the empire. It cannot control teaching, and does not pretend to do so. Nor does it regard or concern itself with the average student of our London medical schools. A Teaching University in London can only come by assimilating our medical schools, and their concentration into a medical faculty under the controlling and directing influences of the Royal Colleges must be the first step toward such a desirable course. Meanwhile the Colleges should take every measure which would pave the way towards obtaining this necessary power, for the number of graduates who are capped grows every year, and the disadvantage of not possessing a degree is ever increasing. A matriculation examination which is more real than the registrable examination of the College of Preceptors or of the Apothecaries' Hall is the first necessity, and with a suitable examination in biology in the first year of study, and perhaps a thesis for the M.D. degree, the present scheme would be put on an honours footing, leaving it as it stands for a pass, whilst those who passed in honours would be fairly and justly entitled to a degree, which would in no way lower those now in existence, but would have a distinct value on its own merits. We trust that the agitation in favour of granting medical degrees to our London students on the same conditions as in the Scotch and provincial universities will not be permitted to wane, but will become stronger and more urgent, so that all our medical candidates may be placed on an equal footing, without being obliged to forego any of the advantages of pursuing their clinical work where opportunities for it are greatest and most readily available.

MEDICAL STUDY ABROAD.

THOUGH there is probably no place in the world where a better and more thoroughly practical acquaintance with disease in all its forms may be obtained than in London, it is well that students—that is to say, more especially advanced students—should be reminded that there are medical schools and universities with abundant and admirable arrangements for teaching medicine across the English Channel, and that much advantage may frequently be gained by a session or more spent at a judiciously selected continental university. There is, too, another and a larger class of readers of THE LANCET to whom some knowledge of foreign medical matters may not come amiss at the present time; we mean the whole body of registered practitioners, who will shortly have to elect representatives to serve on the Medical Council and to help to make and enforce regulations by which the education and practice of British medical practitioners will be governed. It is surely a matter of importance to all who would give intelligent and discriminating votes at the forthcoming election to know something of "how they manage these

Digitized by Google

things" abroad, so that that which is good in foreign systems may be, if possible, assimilated, and that which is inherently bad, or which would be unsuitable to the general conditions of life in these islands, avoided.

The point on which, perhaps, we in this country differ most from our continental brethren is in the matter of preliminary education. Most continental nations require from the medical student some kind of "leaving certificate" showing that he has passed with credit through the highest class or form of a public school, or that he has had an education equivalent to what that would have implied.

In every continental country of importance, for the course for the full licence to practise a knowledge of Greek is compulsory, and generally a much more extensive knowledge of Latin, mathematics, and science than is requisite with us, even for some of the examinations belonging to a grade above the lowest. In France, for example, where the possession of the Bachelor of Letters and the Bachelor of Science (slightly modified) is compulsory on all students who desire the full privileges of practice, the requirements of the double degree may fairly be reckoned as decidedly higher than those of the London matriculation, and as covering more ground than the minimum examinations for Arts degrees at Oxford or Cambridge, though probably the stringency of the tests in the English universities is greater than in France, where nearly everything is *vivâ voce*. A preliminary education about equal to that indicated by an ordinary English university degree in Arts is required also in Germany, Russia, Holland, Austria, Norway, Sweden, Denmark, and Switzerland. In those countries the supply of practitioners is quite equal to the demand, for it is only in very sparsely populated districts that any complaint arises of insufficient medical aid. Indeed, the cry is just the opposite, for foreign medical journals teem, like our own, with lamentations over the increasing number of practitioners and the difficulty experienced both by the juniors and the seniors in finding enough practice. The minimum period of medical study varies considerably in different countries: being four years in France and Spain; four and a half in Germany; five in Austria, Russia, Belgium, and Portugal; six in Italy, Holland, and Denmark; seven in Norway; and ten in Sweden!

Licensing systems vary in different countries. A State examination, other than a university degree, is enforced on all in Germany, Greece, Holland, and Switzerland; also in Belgium on those who have not degrees from the two State universities. A university degree is compulsory in Austria, Denmark, and Italy, and, for the full right to practise, in France. In Norway, Portugal, Russia, Spain, and Sweden, the universities and other medical schools grant licences which constitute titles to practise. In these countries a further examination is required for the Doctorate, which in some cases, as in Norway and Russia, is of so difficult a character that few practitioners attempt it unless they aspire to professorships or important public appointments. The only country where a partial or restricted qualification is now granted is France, where the licence as *officier de santé* only gives the right to practise in the department in which it is conferred, and does not authorise the holder to perform serious surgical operations, except in the presence of a doctor. It, however, requires four years of medical study, or the same period as is necessary for the higher qualification; but the preliminary requirements are very much smaller, and the examinations are not so numerous or so stringent. At the end of the first year, the candidate for the lower grade licence is examined in physics, chemistry, natural history, osteology, and arthrology; at the end of the second year, in descriptive anatomy and physiology; at the end of the third year, in internal and external pathology. At the conclusion of the whole period he is subjected to three *examens definitifs:* the first consisting of anatomy, physiology, and practical dissection; and the second including pathology, therapeutics, materia medica, and operative medicine; the third is a clinical examination in medicine, surgery, and obstetrics. The candidates for the Doctorate have to undergo what may be considered eight examinations of a more advanced character, including, in addition to the subjects required of the *officiers de santé*, hygiene and forensic medicine. They have, besides, to defend a thesis. It may be remarked that the lower grade licence is usually found sufficient by British physicians wishing to practise in French watering-places. Leave can be obtained to undergo the final examinations only.

The German State examination is a very thorough and practical test, or rather series of tests, of the candidate's acquaintance with all branches of medical knowledge. It consists of two main examinations: The "Physicum" takes place after two years' medical study, and is conducted orally and publicly; the subjects are anatomy, physiology, chemistry, physics, botany, and zoology. The Final Examination is conducted by a commission, and before admission to it the candidate must have passed at least four years and a half in professional study, two years of which must have been subsequently to passing the "Physicum" Examination. He must have held appointments in the surgical, medical, obstetrical, and ophthalmic departments, and must have completed two labours in the presence of one of his teachers. The examination embraces anatomy, pathological anatomy and general pathology, surgery and ophthalmology, medicine, midwifery and diseases of women, and hygiene. In anatomy he has to dissect and put up a microscopic preparation; in pathology he must make a partial necropsy; in surgery, medicine, ophthalmology, and midwifery, cases have not only to be examined in presence of the examiner and reported on, but have to be taken charge of for several days under the examiner and full reports handed in daily. A labour has to be attended in the examiner's presence, and, in addition, the candidate is subjected to ordinary *vivâ-voce* tests, and has to perform certain operations on the dead body and on the obstetric phantom. The anatomical and physiological portion must be passed before admission to the other subjects. If the student fail in one of the latter, he may still present himself for the rest, and he may be re-examined in his "weak" subject in from six weeks' to six months' time, according to the degree of weakness. If, however, he should not pass it during the next year he must go through the whole again.

The mode of conducting medical examinations abroad differs somewhat from the plans adopted in this country, papers with several questions on the different subjects

Digitized by Google

being unusual on the Continent, where the written examination—if there should be one—generally consists of extempore essays on some one topic, often drawn by lot, so that a man has a poor chance if he happens to get a theme upon which he knows little, even though he may be pretty well prepared generally. The British system would appear to be fairer, and, to use a students' expression, less liable to "flukes." We pride ourselves rather upon the improvement which has within the last few years been introduced into our clinical examinations, in which one or more patients are actually examined and reported on by the candidate; but even that, as a test, falls far short of the German system mentioned above, of giving candidates charge of cases for several days together, making them report upon the progress and, in case of death, on the post-mortem appearances. In this country it would be difficult to find facilities for this, and impossible to make candidates attend a labour in the examiner's presence.

In the case of most of our licensing corporations the number of times a candidate may fail can, perhaps, only be properly appreciated by "chronic" students and persevering "grinders," or by parents to whom application is made for repeated fees for the same examination. This kind of thing is not tolerated in some countries: for instance, after two failures in Germany and Austria it is difficult to obtain permission for another attempt; and in Austria, if this ends in failure, the unfortunate candidate is permanently debarred from ever obtaining an Austrian qualification, and also from the "nostrification" or recognition of one obtained elsewhere.

Continental universities and medical schools generally are quite willing to allow foreign students or practitioners to attend hospital practice and lectures—in some cases without any payment, in others on payment of lecture fees. Some, too, confer M.D. degrees on English practitioners—after, of course, an examination. Arrangements, for instance, are made in Brussels by which a fully qualified English practitioner can undergo an examination (in English), and, if successful, in a week's time return with the magic letters attached to his name.

Although the Brussels M.D. is the most accessible, it is not by any means the only foreign degree that is open to Englishmen without residence. Paris, Berlin, Naples, and a number of other universities, will accept as sufficient the English medical curriculum, but the examinations imposed are generally conducted in the national language, or possibly in colloquial Latin, and the facilities afforded to a foreigner are therefore not so great as at Brussels. Austrian and Russian degrees can scarcely be obtained by English practitioners.

Licences to practise can be obtained by qualified British practitioners by examination in France, Germany, and Switzerland; and are sometimes granted without examination in Belgium, Italy, and Spain.

RECENT MEDICAL LEGISLATION AND MEDICAL STUDENTS.

IT will naturally be asked if recent medical legislation has any interest for medical students? And, if so, in what way? The essence of the change of law effected by the recent Act, as far as it concerns students immediately, is this: that henceforth, or rather after a certain day in 1887, a person shall not be registered under the Medical Acts in respect of any qualification referred to in any of these Acts, unless he has passed such qualifying examination in Medicine, Surgery, and Midwifery as in this Act mentioned. Clause 3 of the Act defines Qualifying Examinations, and what bodies shall be recognised as holding such examinations. And this is a peculiarity of the Act, that it recognises in any of the existing Universities acting singly the power to grant such a qualifying examination. Whereas, in the case of the corporations, two or more must *combine* to give such a diploma. The combination must not be one of two similar corporations, but one at least of the bodies combining must be a corporation capable of granting a diploma in Medicine, and one at least capable of granting a diploma in Surgery. In other words, the possibility of getting on the Register with a single qualification is abolished. For this purpose it is no use for a corporation to give its diploma singly. Such a diploma could not be registered by itself. This result is much boasted of by those who approve the recent Act. It is no doubt proper that any person getting on the Register should be examined in the three great branches of practice. But this end had been practically gained in all the single corporations before the Act was passed. The English College of Surgeons has long examined in medicine. The London College of Physicians has long boasted of the completeness of its examinations and the doubleness of its diploma. Even the Apothecaries' Society has elected examiners in surgery. The Scotch corporations have always examined in the three branches, and two of the three Irish corporations have done the same. Henceforth, however, the ban of disability rests on corporations acting alone, unless it be the Apothecaries' Societies, for whom it would almost seem a special clause has been introduced into this Act (Clause 5). If the larger corporations refuse to come to terms with the Apothecaries' Societies or to admit them to a scheme for combination or surgical examinations, then they can apply under Clause 5 to the Medical Council for assistant examiners, and with this assistance their examinations may become Qualifying Examinations. Conceivably, then, and probably, there will be three ways of getting on the Register—through the qualifying examination of a university, through the qualifying examination of a combination of corporations, or through the qualifying examination of a corporation assisted by the Medical Council.

Will examinations be more strict under the new law? That remains to be seen. It may be hoped, at any rate, that they will not be less so, and that they will at least be more fairly uniform, and that a qualification in one division of the kingdom will be fairly equivalent to a similar qualification in another. The reason for hoping this is that the Medical Council is made specially responsible for securing the maintenance of the standard of proficiency For this purpose it is to appoint a number of Inspectors for the Qualifying Examinations. We regard this provision of the Act with some interest, and trust that it will conduce to fair play as between one division of the kingdom and another, and between candidates and examining bodies. There is plenty of complaint of bad students. It is possible

Digitized by Google

that good examinations are too few. But with a good staff of well-selected and trained Inspectors better things may be expected.

One important feature of the new Act is the provision for electing Direct Representatives of the profession. The bearing of this on medical students and studies may not be immediately apparent. But we shall be surprised if it does not have some effect, especially if practitioners be elected who look at medical education from the standpoint of actual practice. This is the point for finding out defects in education, and the difference between hospital practice and general practice.

COLLEGIATE RESIDENCES IN LONDON.

FEW can have failed to observe the great difference in social aspect between the present generation of medical students and those which preceded it during the old apprenticeship system. Past medical students came to London with their habits and manners moulded in the country during the period (often four or five years) which they served under the tutelage and supervision of the country doctor. Idleness in the country was followed by idleness and roystering in town—industry by persevering application; and both extremes were well recognised by the profession and the lay public. The medical student of those days was fairly advanced in age, and he but rarely reformed if he had been allowed to run loose and do little or no regular work or reading during his country apprenticeship. If, on the other hand, he had been placed under a judicious master, habits of regularity, punctual attendance, and steady work rarely gave way when he came to town. But since the practical abolition of apprenticeship, the pupil generally passes from his school life into his medical studentship at a bound, and without any intermediate stage. For the first two years of the curriculum he is still in many cases to every intent and purpose a schoolboy, and as such should undoubtedly be more carefully looked after and guarded from evil influences than is either possible or useful in the case of the older student. To meet this many methods of living for students in London have been suggested. The question is of the utmost importance, for the same difficulties have arisen in regard to the theological and legal as with the medical students. The former generation almost always resided in lodgings chosen by themselves and left to themselves, if we except a few who had friends in London, or who boarded and lodged with members of the staff of the medical school or hospital which they attended. Collegiate residences were practically unknown until arrangements were made by the authorities at the foundation of King's and University Colleges for residential students. But with the modification in medical education, necessitating a residence in London during a most impressionable period of life, parents have become much more desirous of supervision of their sons, and the isolated life and absence of restraint have been freely held up of late years as the cause of and an excuse for laziness and other vices. The collegiate system and private care of pupils are in increasing demand, and for these residences—public and private—the registers of lodging-houses, under a quasi-supervision, which are kept by the authorities of many schools, are but a poor substitute. The collegiate system must spread from the four schools which have partially adopted it—viz., St. Mary's, St. Bartholomew's, King's and University Colleges—to the others, and Middlesex is now following in their path. But even in these the number of rooms is very disproportionate to the number of students, although, perhaps, not to the present demand. But this demand will grow larger and become more imperative now that attention has been so publicly and pointedly called to the question. At the older universities residence under supervision is absolute, and the other centres of medical education will be compelled to adopt some similar system. The provincial, Scotch, and Irish schools are in the same position as those of London, and must follow on the same lines.

THE CHOICE OF A TEXT-BOOK.

THE question which the student is always asking, and naturally, is what book will best serve his purpose in preparing for certain examinations. The answer to this question is one which becomes every year more difficult. The number of medical text-books of a high class is now very great; therefore to select a few from amongst them may seem invidious. At the same time a list, which by no means pretends to be exhaustive, can be drawn up that may prove of value as a guide to the student in his choice. As representing all the various examining bodies, we may take for this purpose the Examining Board for England (Royal College of Physicians and Royal College of Surgeons) and the University of London.

THE EXAMINING BOARD FOR ENGLAND.

For the *First* Examination of this Board the student will be required to have gained a fair knowledge of Elementary Anatomy and Physiology, of Chemistry, Materia Medica, and Pharmacy; and if he be diligent he should be able to pass both parts of the examination by the close of his first year. In *Anatomy*, he may have recourse to GRAY'S Text-book, and to the works on *Osteology* by WARD, HOLDEN, and NORTON. In *Physiology*, the Elementary Text-book of HUXLEY might well be mastered first. In *Chemistry*, ROSCOE'S Elementary book and ATTFIELD'S work. In *Chemical Physics*, FOWNES' Inorganic Chemistry edited by WATTS, or BALFOUR STEWART'S Elementary Physics. In *Materia Medica*, the works of MITCHELL BRUCE, ROBERTS, GARROD, and BRUNTON'S or OWEN'S Elements.

For the *Second* Examination (corresponding to the Primary Membership at the College of Surgeons), the subject of *Anatomy* may be well studied in GRAY'S Anatomy, ELLIS'S Demonstrations, or HEATH'S Practical Anatomy. The anatomical plates of ELLIS and those of GODLEE are very useful in supplementing practical work, or the handier volume of MASSE. In *Physiology*, the books most to be recommended are KIRKES' Handbook, G. YEO'S Text-book, and H. POWER'S Elements; and *Histology*, apart from the sections devoted to it in the works of GRAY and KIRKES, may be read in KLEIN'S Elements.

For the *Third* or Final Examination, in the subjects of *Surgery* and *Surgical Anatomy*, there are the Text-books of BRYANT, HOLMES, GANT, and ERICHSEN'S work, ably edited by MARCUS BECK, the System of Surgery edited by TREVES, the Practical Handbooks of BERKELEY HILL, CHRISTOPHER HEATH, PEARCE GOULD, and TREVES'S Applied Surgical

Digitized by Google

Anatomy. For *Surgical Pathology* PEPPER or BILLROTH may be recommended. In *Diseases of the Eye*, LAWSON or NETTLESHIP. In *Medicine*, the Text-books of ROBERTS and BRISTOWE, preceded by the smaller works of CARTER or CHARTERIS. *Clinical Medicine:* FENWICK, FINLAYSON, or GRAHAM BROWN. *Pathology:* GREEN, COATS, and ZIEGLER (MACALISTER'S translation), and WOODHEAD'S practical work. *Therapeutics:* BARTHOLOW, RINGER, NAPHEYS, and FARQUHARSON. *Medical Jurisprudence:* the Text-books of GUY and TAYLOR. *Public Health:* WILSON. *Midwifery:* PLAYFAIR or GALABIN.

COLLEGE OF SURGEONS (FELLOWSHIP).

In addition to the anatomical and physiological works above mentioned, there may be read for the Primary F.R.C.S. (especially its histological and embryological sections)—QUAIN'S Anatomy, FOSTER'S Text-book of Physiology, LANDOIS' work edited by STIRLING, and GEGENBAUR'S Comparative Anatomy. Professor FLOWER'S Osteology of the Mammalia might also be read. For the Pass Examination, ERICHSEN'S work may be supplemented by chapters in the System of Surgery edited by HOLMES and HULKE. In *Operative and Practical Surgery*, there are works by STIMSON, FERGUSSON, and S. SMITH and HEATH'S ATLAS. PAGET'S or BILLROTH'S Surgical Pathology and ZIEGLER'S Pathology may be profitably read in connexion with works mentioned under the Conjoint Examination.

UNIVERSITY OF LONDON EXAMINATIONS.

For the Intermediate M.B. Examination of the University of London, the subject of *Organic Chemistry* may be studied in the Text-books of WILLIAMSON and of FOWNES. *Materia Medica*, besides the books above mentioned, is more fully treated in the works of BRUNTON, PHILLIPS, BARTHOLOW, and H. G. WOOD. *Physiology* as for the Primary F.R.C.S., with perhaps the addition of such books as that of POWER and HARRIS for practical work and of SCHAEFER for practical histology. The anatomical text-books are those recommended above. For the M.B. Examination, the subject of *Medicine* may profitably be further studied in NIEMEYER'S Text-book, in the exhaustive and scientific treatise of the late Dr. HILTON FAGGE, in that of AUSTIN FLINT, in REYNOLDS'S System of Medicine, and in TROUSSEAU'S Lectures. Special monographs (see M.D. Exam.) may also be consulted. *Pathology*, which should be worked at practically, may be studied in GREEN'S, COATS', or ZIEGLER'S Text-books, and also in the works of WILKS and MOXON, and in those of CORNIL and RANVIER; *Midwifery*, in the writings of PLAYFAIR, GALABIN, LEISHMAN, LUSK, and BARNES; *Gynæcology*, in those of GALABIN, LOMBE ATTHILL, EDIS, M. JONES, and BARNES; *Dermatology*, in the Text-books of TILBURY FOX, LIVEING, DUHRING, and M. MORRIS; *Medical Electricity*, in DE WATTEVILLE or POORE; *Medical Ophthalmoscopy*, in GOWERS' Handbook. For the M.D. Examination the candidate will do well to extend his reading to the better-known monographs, such as MURCHISON on Continued Fevers and on Diseases of the Liver; ROSS, CHARCOT, and WILKS on Diseases of the Nervous System; BALFOUR, BYROM BRAMWELL, and WALSHE on Diseases of the Heart; POWELL and WALSHE on Diseases of the Lungs; RALFE, W. ROBERTS, and DICKINSON on Diseases of the Kidney.

In the foregoing lists we have mostly indicated more than one work upon a subject; for it is, of course, impossible to make a single selection from among so large a number of excellent works. A certain amount of choice must be left to the student himself, who will do well to be guided in this respect by the opinion of his teacher in the particular subject.

ARMY, NAVY, AND INDIAN MEDICAL SERVICES.

THESE three branches of the public medical service maintain their popularity with the junior members of the profession, if we may judge by the numbers of candidates who present themselves at the competitive examinations held twice a year. If we mistake not, they were in the proportion of two candidates for each vacancy at the examination in August. These services certainly offer some very appreciable advantages, either as a career for life or as a temporary occupation for a few years. After a successful competition at the examination in London, the "surgeon on probation" for the Army and Indian Service is sent to Netley to undergo a course of special training for a period of four months, during which he receives pay at the rate of 8*s.* a day, with free quarters. We consider this course, which includes Military Surgery, Military Medicine, Pathology, and Hygiene, to be of great value. On its conclusion, the "surgeon on probation" is gazetted to the medical staff or Indian Medical Service as Surgeon, with the relative rank of Captain. In the Navy, the successful candidate is sent at once to Haslar and gazetted as Surgeon. He undergoes there a certain amount of special instruction, but we believe it is not at all to be compared with that given at Netley. The advantages of the public service are that the medical officer starts at once on his career with a fair amount of income, which is totally independent of the caprice or goodwill of his patients; that he goes on with the certainty of an increase of pay and improved position after a certain number of years, and, if he continue in the service, with a retiring pension after twenty years proportionate to the length of time he has served and the rank he has attained; or, if he wish to quit it sooner, he can do so at any time, receiving a gratuity after ten, fifteen, or eighteen years. The drawbacks to the service undoubtedly are the amount of foreign service and consequent absence from England, which must fall to the lot of all officers, and the unhealthy climates in which they may be called upon to serve; but this also has its attractions for those who care to be in foreign lands, and who are desirous of investigating the various forms of tropical disease, or who have a bias for the study of natural history. We cannot but think that the public services, as at present organised, offer a career which is well deserving the consideration of medical students who have not any special local ties or exceptional prospects of success in civil life.

PUBLIC HEALTH QUALIFICATIONS.

MR. EDWIN COONEY, hon. secretary to the Association of Medical Practitioners qualified in Sanitary Science, has favoured us with the following information.

As Public Health Qualifications have now received State recognition and are so much to the fore, perhaps a few statistics or particulars referring to such may not be out of place. By referring to the subjoined table, it will be ob-

Digitized by Google

served that Trinity College, Dublin, commenced granting such qualifications as early as 1871, and since then the aggregate annual number has increased, with a notable falling off from 1878 to 1880. For the present year, it is not certain what the number will be, as most of the qualifications are given from September to December. Up to the present time 233 qualifications have been given, but as nine men hold two qualifications each, there are about 224 qualified. Edinburgh has given forty-five degrees, but as eight have proceeded from B.Sc. to D.Sc., thirty-seven only are noted:—

Total.	1	3	3	6	7	7	8	12	25	37	124	233

The distribution of those holding these qualifications are as follows: London, 52; Provinces, 90; Scotland, 16; Ireland, 16; Indian Medical Service, 22 (Bengal 15, Bombay 3, Madras 3); Army Medical Department, 11; Australia, 5; India, 3; France, 1; New Zealand, 1; Canada, 1; West Indies, 1; not known, 5.

Twelve out of fifteen bodies are granting Public Health qualifications. Of these, four are called Certificates in Public Health (Univs. Oxf. and Lond., Roy. Coll. Phys. Edin., F.P.S. Glas.); three are called Sanitary Science Certificates (Univs. Camb. and Durh., K.Q.C.P. Irel.); one is called B.Sc. or D.Sc. in Public Health (Univ. Edin.); one, Qualification in Public Health (Univ. Glas.); one, Diploma in State Medicine (Trin. Coll. Dub.); one, Diploma in Sanitary Science (Roy. Univ. Irel.); and one, Certificate in Hygiene (Roy. Coll. Phys. Lond.). It is not quite certain what the whole of the respective holders of these certificates, degrees, diplomas, and qualifications in Hygiene, Public Health, Sanitary Science, and State Medicine are to be called now that Public Health diplomas are registrable under Clause 21 of the Medical Act, 1886. The Irish Universities style their men "Diplomates," and the Edinburgh University "Bachelor" or "Doctor."

We gladly give publicity in the Students' Number to this interesting statement, which shows very clearly the increasing number of medical men who are certified by different educational bodies to have a special knowledge of Sanitary Science. The subject is one of much importance, because it may be anticipated that local authorities will regard with favour those who can claim to possess such qualifications. As yet the teaching of Hygiene and Public Health has not been regarded as of sufficient importance to necessitate special arrangements being made at all medical schools for a thorough course of instruction in this branch of professional knowledge. In another part of this Number will be found the tabular list of the classes, lecturers, &c., at the different medical schools, and students who may anticipate that in the future they may be called upon to hold Public Health appointments will necessarily have regard, in their selection of a school, to the arrangements which are made in each for the teaching of this subject.

THE ADVANTAGES OF THE STUDY OF PSYCHOLOGY.

IT is strange, but true, that although many of our examining bodies would never dream of permitting a student to practise medicine, surgery, or obstetrics unless he had given ample proofs of his qualification, yet he is allowed to incarcerate Her Majesty's subjects in an asylum without any proper evidence having been adduced that he possesses the requisite knowledge of insanity or of the laws which bear upon this most important branch of medicine. But few students recognise the advantages of a knowledge of lunacy. It may of course be said that only a few can attain to the envied post of superintendent of an asylum, that those who already have reached this summit of ambition are picked men, selected out of a large number of applicants by a severe system of competition; that, in fact, the race is to the swift, the battle to the strong. But it is not to this class of aspirants that we wish to address our remarks. It is rather to the general practitioner, he whose industry is rightly said to form the backbone of the profession, and to whom in the first instance the family fly for advice when one of their relatives becomes afflicted with unsoundness of mind. Such men, we regret to say, when they leave the schools, may have never seen a lunatic; they may have never been instructed in the simple act of filling up a certificate, and in consequence a large percentage of these certificates are returned as invalid. Then, again, with regard to the dangers incurred by those who ignorantly fill up these certificates. The records of the daily papers sufficiently prove that the pocket of the certifier may be seriously affected should he omit some apparently trivial and red-tape matter of detail, which is probably mentioned in the marginal notes. A certificate has been found invalid in a court of justice simply because the number of the house in which the patient resided was omitted from the "form." Some practitioners wisely abstain from signing

Digitized by Google

certificates at all. Of late some action has been taken in the matter, and the Royal College of Physicians of London, the London University, the Society of Apothecaries, the Royal College of Physicians of Edinburgh, and, we believe, other qualifying bodies, have instituted an examination in psychological medicine; at most of our medical schools there now exists a course of lectures on insanity. And we have reason to believe that so far the work has been satisfactorily done. But we wish more especially to point out to students that should they require additional proof of their knowledge in mental therapeutics, whether with the object of seeking those coveted appointments to which we have already alluded, or simply with a view to protect themselves from litigation, now is the time to prove that they are in earnest. Quite recently the Medico-Psychological Association has established an examination for a certificate in psychological medicine, information regarding which can be obtained from any of the lecturers on insanity at our metropolitan schools. The details concerning the certificate are also given in full in the *Journal of Mental Science* for July. Briefly, the candidates must be twenty-five years of age, must have resided as clinical clerk or assistant medical officer in an asylum for at least three months, and must, of course, be duly registered. The examination is chiefly practical, no knowledge of mental philosophy or of microscopical anatomy being required. The idea has doubtless been taken from the success which has attended the establishment of a certificate in hygiene at Cambridge and at the College of Physicians. We have every reason to believe that the electing bodies for appointments of medical officers of health lay great stress upon the fact that a candidate has a special knowledge of the work he is about to undertake. And in the present day, when the public interest themselves far more about medical matters than was the case in the time of our grandfathers, it is reasonable to conclude that those who have availed themselves of the opportunities which now offer will have surely a better chance of attaining to the desired post of director of an asylum, and also will be more likely to secure the confidence of the relatives of a lunatic, if they can prove that they possess a knowledge of mental disease. We are glad to find that the tests for the certificate we have mentioned include the clinical examination of insane patients, and also that candidates are required to properly fill up medical certificates.

DENTAL EDUCATION.

DENTAL SURGERY has been attracting considerable attention of late years, and its practice rapidly gaining favour. The odium with which it was regarded on account of the large number of, to say the least, uneducated men who filled the ranks, has to a great extent been removed, and will entirely disappear now that no one will be allowed to call themselves Dental Surgeon without a diploma. For a student with a mechanical turn, the manipulations, the constant demands for the display of ingenuity, and the endless variations of the operations in dental surgery must have a great charm. One great advantage is that a man gets into practice earlier than in most other branches of the medical profession. In these days when long and elaborate operations are becoming more and more the practice, the capability of considerable endurance, both mental and physical, is required by the dentist.

In order to be legally entitled to practise it is not necessary that the student should have any diploma but that in Dental Surgery; but we would strongly urge anyone who hopes to attain a high rank in his profession, and who values his future social position, to add a medical qualification; and he cannot do better than take the L.R.C.P. and M.R.C.S. under the Conjoint Scheme, and we will briefly sketch how this may be effected.

The regulations for the diploma in Dental Surgery of th College of Surgeons of England, apart from those included in the general hospital course, are that the candidate should have been engaged in the acquirement of professional knowledge during four years; have attended at a recognised school two courses of lectures upon each of the following subjects—viz., Dental Anatomy and Physiology (Human and Comparative) Dental Surgery, Dental Mechanics, and one course of lectures on Metallurgy by lecturers recognised by the College; have been engaged, during a period of not less than three years, in acquiring a practical familiarity with the details of Mechanical Dentistry, under the instruction of a competent practitioner, except in the cases of qualified surgeons, when not less than two years instead of three will be sufficient; and, lastly, of having attended at a recognised dental hospital, or in the dental department of a recognised general hospital, the practice of Dental Surgery during the period of two years.

If the student have already passed the matriculation of the University of London or other examination allowed by the Medical Council, he must register as a *dental* student. The next step is to become articled to a registered dental surgeon, and upon the training received during this period will largely depend his future success in that important branch—Dental Mechanics, &c. It is the unanimous opinion that the three years prescribed by the College of Surgeons is not a day too long to enable the student to master its details. If a preliminary examination has not been passed, the student should nevertheless take up his articles, and present himself for such examination during the first or second year of his pupilage; for, by the regulations of the Medical Council, the three years' instruction in Mechanical Dentistry, or any part of them, may be taken by the dental student either before or after his registration; but no such year of mechanical instruction shall be counted as one of the four years of professional study unless taken after registration. Immediately he has passed the preliminary he should register as a dental student.

During his pupilage the student should familiarise himself with most of the subjects required for the First Professional Examination—Chemistry, Chemical Physics, Materia Medica, Elementary Anatomy, and Physiology, and more especially Dental subjects,—so that when he joins the hospitals his work may be more easy for him, and also that he may not during his apprenticeship "forget how to learn." This part of his career finished, the student should join a general hospital and register as a *medical student*. A word about the choice of a general hospital. It is of undoubted advantage to enter a school where there are several other men taking the same course; it is also convenient that the general and dental hospitals should be near together.

Digitized by Google

For the course of instruction to be pursued at the general hospital reference should be made to another portion of this journal. The student should join the dental hospital after having passed the Second Professional Examination, which should, supposing he joined in October, be at the commencement of the second summer session. During this session, one course of lectures on Dental Surgery and Pathology and one on Dental Anatomy and Physiology and Dental Hospital Practice must be attended. During the third winter, one course on Dental Mechanics and Dental Hospital Practice. In the third summer, one course on Dental Surgery and Pathology, and one on Dental Anatomy and Physiology and Dental Hospital Practice. And in the fourth winter, one course on Dental Mechanics, and one on Metallurgy and Dental Hospital Practice.

SESSION 1886-87.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

Registration of Medical Students.—The following are the General Medical Council's Regulations in reference to the registration of students in medicine:-

Every medical student shall be registered in the manner prescribed by the General Medical Council. No medical student shall be registered until he has passed a preliminary examination as required by the General Medical Council,[1] and has produced evidence that he has commenced medical study. The commencement of the course of professional study recognised by any of the qualifying bodies shall not be reckoned as dating earlier than fifteen days before the date of registration. The registration of medical students shall be placed under the charge of the branch registrars. Each of the branch registrars shall keep a register of medical students according to a prescribed form, and shall enter therein the name, the preliminary examination and date thereof, the date of registration, and the place and date of commencement of medical study, as certified by a master or a teacher, or an official in a medical school or hospital. Every person desirous of being registered as a medical student shall apply to the branch registrar of the division of the United Kingdom in which he is residing; and shall produce or forward to the branch registrar a certificate of his having passed a preliminary examination as required by the General Medical Council, and *evidence that he has commenced medical study*. The branch registrar shall enter the applicant's name and other particulars in the Students' Register, and shall give him a certificate of such registration. Each of the branch registrars shall supply to the several qualifying bodies, medical schools, and hospitals, in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of medical students. The several Branch Councils—and in England the Executive Committee, if its meeting be more convenient and the case be urgent—have power to admit special exceptions to the foregoing regulations as to registration, for reasons which shall appear to them satisfactory. A copy of the Register of Medical Students, prepared by each of the branch registrars, shall be transmitted on or before December 31st, in each year, to the registrar of the General Council, who shall, as soon as possible thereafter, prepare and print, under the direction of the Executive Committee, an alphabetical list of all students registered in the preceding year, and supply copies of such authorised list to each of the bodies enumerated in Schedule A to the Medical Act (1858), and through the branch registrars to the several medical schools and hospitals. The several qualifying bodies are recommended not to admit to the final examination for a qualification under the Medical Acts any candidate (not exempted from registration) whose name has not been entered in the Medical Students' Register at least forty-five months previously. In the case of candidates from other than schools of the United Kingdom, the Branch Councils—and in England the Executive Committee, if its meeting be more convenient and the case be urgent—have power to admit exceptions to this recommendation.

Pursuant to resolutions passed by the General Medical Council at its meetings on October 16th, 1884, and May 14th, 1885, the Regulations for Preliminary General Education, which take effect from October 1st, 1885, are as follows:—

On and after October 1st, 1885, no person shall be allowed to be registered as a medical student unless he shall have previously passed (at one or more examinations) a preliminary examination in the subjects of general education as specified in the following list:—1. English Language, including Grammar and Composition. 2. Latin, including Grammar, Translation from specified authors, and Translation of easy passages not taken from such authors. 3. Elements of Mathematics, comprising (*a*) Arithmetic, including Vulgar and Decimal Fractions; (*b*) Algebra, including Simple Equations; (*c*) Geometry, including the first book of Euclid, with easy questions on the subject matter of the same. 4. Elementary Mechanics of Solids and Fluids, comprising the Elements of Statics, Dynamics, and Hydrostatics. 5. One of the following optional subjects:—(*a*) Greek, (*b*) French, (*c*) German, (*d*) Italian, (*e*) any other Modern Language, (*f*) Logic, (*g*) Botany, (*h*) Zoology, (*i*) Elementary Chemistry.[2]

W. J. C. Miller, B.A., Registrar of the General Council and of the Branch Council for England, 299, Oxford-street, London, W.—James Robertson, Registrar of the Branch Council for Scotland, 4, Lindsay-place, George IV. Bridge, Edinburgh.—R. L. Heard, M.D., Registrar of the Branch Council for Ireland, 35, Dawson-street, Dublin.

REGULATIONS OF THE MEDICAL EXAMINING BOARDS IN THE UNITED KINGDOM.

UNIVERSITY OF OXFORD.

A student may take the degree of Bachelor of Medicine after he has been admitted to the degree of Bachelor of Arts, provided that he has passed the examinations prescribed for the B.M. degree.

For the B.A. degree a student must have kept the statutable residence—viz., twelve terms (three years) from his matriculation; and after passing Responsions and the First Public Examination must take honours in one of the seven Honour Schools, or pass the examination appointed for those who do not seek honours. The limit of time for honours in the Second Public Examination is sixteen terms, but if the candidate has taken honours in one of the schools the time is extended to twenty terms.

There are two examinations for the B.M. degree. The subjects of the First Examination are:—(1) Organic Chemistry in its special relation to Physiology and Medicine, (2) Human Anatomy, and (3) Human Physiology. Candidates who have taken a first- or second-class in Organic Chemistry or Animal Physiology are exempted from the corresponding part of the M.B Examination. The subjects of the Second Examination are: (1) Medicine, (2) Surgery, (3) Midwifery, (4) Pathology, (5) Forensic Medicine, and (6) Materia Medica and Pharmacy.

The subjects of Organic Chemistry and Materia Medica and Pharmacy may be taken alone, and the other subjects passed at a future examination.

The examinations are held yearly in the Trinity Term, the latter part of the Summer Term.

Any person who has taken the B.M. degree may supplicate

[1] Exception may be made in the case of a student from any Indian, Colonial, or Foreign University or College, who shall have passed the matriculation or other equivalent examination of his University or College, provided such examination fairly represents a standard of general education equivalent to that required in this country.

[2] In the case of students in Universities with a prolonged curriculum, where the examination in Mechanics required for their degree is taken at a more advanced period of study than before commencing medical education, registration can be effected only on having passed the examination in Mechanics, but their registration may be then antedated to the period at which the Preliminary was passed.

Digitized by Google

for the degree of Doctor of Medicine, provided that he has entered on the thirty-ninth term from his matriculation, and that his name has been on the books of some College or Hall, or on the Register of Non-collegiate Students, for twenty-six terms, and that he has written a dissertation, which he shall deliver to the Regius Professor of Medicine.

Every person admitted to the degree of Bachelor of Medicine shall, *ipso facto*, be admitted to the degree of Bachelor of Surgery. He can supplicate for the degree of Master of Surgery after the twenty-sixth term from his matriculation, provided his name has been on the books twenty-six terms, and he has passed an examination in Surgery, Surgical Anatomy, and Surgical Operations, which will be held in Trinity Term, after the Second Examination for the B.M. degree.

More detailed information may be obtained from the University Calendar: the University Statutes, 1886; from the Student's Handbook to the University; from the Regius Professor of Medicine; from the Professors in the several departments; and from the Sub-Librarian in the Radcliffe Library at the Museum.

UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep terms for three years by residence in the University. He must pass the Previous Examination in Classics and Mathematics, which may, and should if possible, be done immediately on coming into residence in October, or, which is best, obtain exemption through the Oxford and Cambridge Schools Examination Board or the Local Examinations, before commencing residence. He may then devote himself to medical study in the University, attending the hospital and the medical lectures, dissecting, &c. Or he may proceed to take a degree in Arts, either continuing mathematical and classical study and passing the ordinary examinations for B.A., or going out in one of the Honour Triposes. The Natural Sciences Tripos is the most appropriate, as the subjects are the same as those for the First and Second M.B. Examinations.

For the degree of *Bachelor of Medicine* five years of medical study are required, except in the case of medical students who have graduated with honours as Bachelors of Arts, four years only being then required, though it is rarely sufficient. This time may be spent in Cambridge or elsewhere. The first three or four years are usually spent in Cambridge, the student remaining in the University till he has passed (say) the examination for the Natural Sciences Tripos and the first and second examinations for M.B. Cambridge being now a complete School of Medicine, all the requisite lectures and hospital practice may be attended here, and many students remain to attend lectures and hospital practice until they have passed the first part of the third examination for M.B. The supply of subjects for Dissection and Practical Surgery is unusually abundant.

There are three examinations for M.B. The *first* in Chemistry and other branches of Physics, and in Elementary Biology. These may be taken together or separately. The *second* in Human Anatomy and Physiology, and in Pharmacy and Pharmaceutical Chemistry. These may be taken together or separately. The *third* may be also taken in two parts—viz., (1) Principles of Surgery (with Clinical Surgery) and Midwifery and Diseases of Women, and (2) Pathology, Principles and Practice of Medicine, Elements of Hygiene, and Medical Jurisprudence. The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting-room, and in the laboratories.

Previously to the first examination, lectures must have been attended on Chemistry (with manipulations). Previously to the second examination, the student must have attended Lectures on Human Anatomy, Pharmacy and Pharmaceutical Chemistry, and Physiology, have dissected for six months, and attended Hospital Practice six months. Previously to the first part of the third examination, he must have attended Lectures on Pathological Anatomy, the Principles of Surgery and Midwifery, the Surgical Practice of a Hospital with Clinical Lectures for a year, ten cases of Midwifery, and produce a certificate of proficiency in Vaccination. Previously to the second part of the third examination, he must have attended Lectures on the Principles and Practice of Physic, the Physiological Action and Therapeutic Uses of Drugs, and Medical Jurisprudence; also the Medical Practice of a Hospital with Clinical Lectures for three years, and have been Clinical Clerk for six months.

The degree of *Doctor in Medicine* may be taken three years after that of M.B. An Act has to be kept, with *viva-voce* examination; and an extempore essay has to be written on some subject relating to Physiology, Pathology, the Practice of Medicine, or State Medicine.

The candidate for the examination for the degree of *Bachelor of Surgery* (B.C.) is required to have passed the *first* and *second* examinations, and the first part of the *third* examination for M.B.; to have attended the Surgical Practice of a Hospital for two years, have acted as House-Surgeon or Dresser for six months, and have gone through a course of instruction in Practical Surgery. The subjects of the examination are Surgical Operations and the application of Surgical Apparatus; the Examination of Surgical Patients is now included in the first part of the *third* examination for M.B. Before *admission* to the degree he must also have passed the *second* part of the third examination for M.B.

For the degree of *Master in Surgery* (*M.C.*) the candidate must have passed all the examinations for B.C. two years. He is required to pass an examination in Surgical Anatomy and Surgical Operations, Pathology, and the Principles and Practice of Surgery.

An abstract of the Regulations and Schedules of the range of the examinations in Chemistry, Physics, Biology, and Pharmacy may be obtained by sending a stamped directed envelope to the Assistant-Registrar, Cambridge. Full information is contained in the *Cambridge University Calendar*.

UNIVERSITY OF LONDON.

The *Matriculation Examinations* take place on the second Monday in January and the third Monday in June. Candidates must be above sixteen years of age. The fee for the examination is £2. Provincial examinations are appointed by the Senate from time to time at specified centres. Several scholarships, exhibitions and prizes are associated with these examinations.

The *Preliminary Scientific (M.B.) Examination* takes place twice in each year, commencing on the third Monday in July and the third Monday in January.[3] No candidate will be admitted to this examination until he shall have passed the Matriculation Examination, nor unless he have given notice of his intention to the registrar at least one calendar month before the commencement of the examination. Fee for this examination, £5.

Candidates are examined on the following subjects:—Inorganic Chemistry, Experimental Physics, and General Biology. Candidates for Honours, who have entered for the whole examination, may also be examined in Botany and Vegetable Physiology, and Zoology, unless they have previously obtained an exhibition in any one of the subjects of this examination at the Intermediate Examination in Science, in which case they shall not be admissible to the examination for Honours in that subject.

Bachelor of Medicine.—Every candidate for the degree of Bachelor of Medicine will be required—1. To have passed the Matriculation Examination in this University. 2. To have passed the Preliminary Scientific Examination. 3. To have been engaged in his professional studies during four years subsequently to passing the Preliminary Scientific Examination[4] at one or more of the medical institutions or schools recognised by this University, one year at least of the four to have been spent in one or more of the recognised institutions or schools in the United Kingdom. 4. To pass two examinations in Medicine.

Intermediate Examination.—The Intermediate Examination in Medicine takes place twice in each year, once for Pass and Honours, commencing on the second Monday in July, and once for Pass candidates only, commencing on the third Monday in January, the January examination being held for the first time in 1888. No candidate shall

[3] Candidates for the degree of M.B. are required after Jan. 1st, 1885, by the Senate to pass the Preliminary Scientific Examination before commencing their regular medical studies, and are recommended to devote a preliminary year to preparation for it, according to the following programme:—Winter Session: Experimental Physics, Chemistry (especially Inorganic), Zoology. Summer Session: Practical Chemistry (Inorganic), Botany.

[4] Candidates who passed the Matriculation Examination in January, 1885, or previously, will be allowed to date the commencement of their professional studies, as heretofore, from that examination.

Digitized by Google

be admitted to this examination unless he have passed the Preliminary Scientific Examination at least two years previously, and have produced certificates to the following effect:—1. Of having completed his nineteenth year. 2. Of having, subsequently to having passed the Matriculation Examination, been a student during two years at one or more of the medical institutions or schools recognised by this University, and of having attended a course of lectures on each of three of the subjects in the following list: Descriptive and Surgical Anatomy, Histology and Physiology, Pathological Anatomy, Materia Medica and Pharmacy, General Pathology, General Therapeutics, Forensic Medicine, Hygiene, Obstetric Medicine and Diseases peculiar to Women and Infants, Surgery, Medicine. 3. Of having, subsequently to having passed the Preliminary Scientific Examination, dissected during two winter sessions. 4. Of having, subsequently to having passed the Preliminary Scientific Examination, attended a course of Practical Chemistry, comprehending practical exercises in conducting the more important processes of General and Pharmaceutical Chemistry, in applying tests for discovering the adulteration of articles of the Materia Medica and the presence and nature of poisons, and in the examination of mineral waters, animal secretions, urinary deposits, calculi, &c. 5. Of having attended to Practical Pharmacy, and of having acquired a practical knowledge of the preparation of medicines. These certificates (as is the case also with all the certificates hereinafter mentioned) must be transmitted to the registrar at least fourteen days before the commencement of the examination. Fee for this examination, £5.

Candidates will be examined in the following subjects: Anatomy, Physiology, Histology, Materia Medica and Pharmaceutical Chemistry, and Organic Chemistry.

Every candidate for the July examination, on sending in his name for the examination, must state whether he intends to compete for Honours in any subject or subjects; and, if he does so intend, must specify the subject or subjects. No candidate will be allowed to take both the Pass and the Honours Papers in the same subject; but every candidate must take the Pass Papers in those subjects in which he does not offer himself for Honours. A candidate who enters for, but fails to obtain, Honours in any subject, may be recommended by the examiners for a Pass in that subject if they are satisfied that he has shown such a competent knowledge thereof as is required by the regulations for the Pass Examination.

M.B. Examination.[5]—The M.B. Examination takes place once in each year, and commences on the last Monday in October. Each candidate, two academical years after passing the First Examination, must produce certificates to the following effect:—1. Of having passed the Intermediate Examination. 2. Of having, subsequently to having passed the Intermediate Examination, attended a course of lectures on each of two of the subjects enumerated in Section 2 of the regulations for that examination, and for which the candidate had not on that occasion presented certificates. 3. Of having conducted at least twenty labours. Certificates on this subject will be received from any legally qualified practitioner in Medicine. 4. Of having attended the Surgical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Surgery. 5. Of having attended the Medical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Medicine. 6. Of having, after having attended Surgical and Medical Hospital Practice for at least twelve months subsequently to passing the Intermediate Examination, attended to Practical Medicine, Surgery, or Obstetric Medicine, with special charge of patients, in a hospital, infirmary, dispensary, or parochial union, during six months, such attendance not to be counted as part of either the Surgical or the Medical Hospital Practice prescribed in Clauses 4 and 5. 7. Of having acquired proficiency in Vaccination. Certificates on this subject will be received only from the authorised vaccinators appointed by the Privy Council. The candidate must also produce a certificate of moral character from a teacher in the last school or institution at which he has studied, as far as the teacher's opportunity of knowledge has extended. The fee for this examination is £5.

[5] Any candidate for the M.B. Examination who has passed the Intermediate Examination under the former regulations will be required to have also passed the examination in Physiology at some previous Intermediate Examination carried on under the present regulations, at which examination he shall not be allowed to compete for Honours.

Candidates will be examined in the following subjects: General Pathology, General Therapeutics and Hygiene, Surgery, Medicine, Obstetric Medicine, Forensic Medicine. The examinations will include questions in Surgical and Medical Anatomy, Pathological Anatomy, and Pathological Chemistry.

Any candidate who has passed the M.B. Examination may be examined at the Honours Examination next following the M.B. Examination at which he has passed for Honours in (1) Medicine, (2) Obstetric Medicine, and (3) Forensic Medicine. The examinations commence in the week following that in which the Pass Examination terminated. Except in the case of Forensic Medicine, they are conducted by means of printed papers, but the examiners will not be precluded from putting *viva-voce* questions upon the written answers of the candidates.

Bachelor of Surgery.—The examination for the degree of Bachelor of Surgery takes place once in each year, and commences on the Tuesday following the first month in December. Candidates must produce certificates to the following effect:—1. Of having passed the examination for the degree of Bachelor of Medicine in this University. 2. Of having attended a course of instruction in Operative Surgery, and of having operated on the dead subject. Fee for this examination, £5.

Any candidate who has passed the B.S. Examination may be examined at the Honours Examination next following the B.S. Examination at which he has passed for Honours in Surgery. The examination takes place on Tuesday in the week following the Pass Examination, and is conducted by means of printed papers.

Master in Surgery.—The examination for the degree of Master in Surgery takes place once in each year, and commences on the first Monday in December.

Candidates must produce certificates to the following effect:—1. Of having taken the degree of Bachelor of Surgery in this University.[6] 2. Of having attended, subsequently to having taken the degree of Bachelor of Surgery in this University, (*a*) to Clinical or Practical Surgery during two years in a hospital or medical institution recognised by this University; or (*b*) to Clinical or Practical Surgery during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession; or (*c*) of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Surgery in this University. One year of attendance on Clinical or Practical Surgery, or two years of practice, will be dispensed with in the case of those candidates who at the B.S. Examination have been placed in the first division. 3. Of moral character, signed by two persons of respectability.

Fee for this degree, £5. The examination is conducted by means of printed papers and *viva-voce* interrogation.

Candidates will be examined in Logic and Psychology, or in Mental Physiology, and in Surgery.

Doctor of Medicine.—The examination for this degree takes place once in each year, and commences on the first Monday in December.

Candidates must produce certificates to the following effect:—1. Of having passed the examination for the degree of Bachelor of Medicine in this University. 2. Of having attended, subsequently to having taken the degree of Bachelor of Medicine in this University, (*a*) to Clinical or Practical Medicine during two years in a hospital or medical institution recognised by this University; or (*b*) to Clinical or Practical Medicine during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession; or (*c*) of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Medicine in this University. One year of attendance on Clinical or Practical Medicine or two years of practice will be dispensed with in the case of those candidates who at the M.B. Examination have been placed in the first division. 3. Of moral character, signed by two persons of respectability.

[6] Candidates who have obtained the degree of Bachelor of Medicine previously to 18'6 will be admitted to the examination for the degree of Master in Surgery without having taken the degree of Bachelor of Surgery; and in the case of such candidates the attendance on surgical practice required by Regulation 2 may commence from the date of the M.B. degree.

Digitized by Google

Fee for this degree, £5.[7] The examination is conducted by means of printed papers and *viva-voce* interrogation.

Candidates will be examined in Logic and Psychology, or in Mental Physiology, and in Medicine.

UNIVERSITY OF DURHAM.

A Certificate, two Licences, and three Degrees are conferred—viz., a certificate of Proficiency in Sanitary Science, a Licence in Medicine, and a Licence in Surgery; and the Degrees of Bachelor in Medicine, Master in Surgery, and Doctor in Medicine.

For the degree of *Bachelor in Medicine* (*M.B.*) there are three professional examinations: the first being held in September (in 1887, commencing on the 19th) and April (in 1887, commencing on the 18th); the second in September (in 1887, commencing on the 26th) and April (in 1887, commencing on the 25th; and the third in December (in 1886, commencing on the 6th) and in June (in 1887, commencing on the 13th).

The subjects for the first examination are—Elementary Anatomy and Elementary Physiology, Chemistry, with Physics, and Botany. Candidates must produce the following certificates:—(1) Of registration as a medical student. (2) Of attendance on the following courses of lectures: Anatomy, Physiology, Chemistry, with Physics, and Practical Anatomy (Dissections), each six months; Botany and Practical Chemistry, each three months. The subjects for the second examination are Anatomy, Physiology, Materia Medica, with Pharmacy. For it the following certificates are necessary: Lectures, &c.—Anatomy, Physiology, Practical Anatomy (Dissections), second courses of six months each; Materia Medica, Practical Physiology, and Practical Pharmacy, courses of three months each. The candidate must also produce a certificate of his having passed the first examination for the M.B., or the first examination of the Conjoint Board of the Royal College of Physicians of London, and the Royal College of Surgeons of England, together with the extra examinations in Chemistry and Botany of the University of Durham.

The subjects for the third examination are Medicine, Surgery, Pathology, Therapeutics, Midwifery and Diseases of Women and Children, Medical Jurisprudence, and Public Health. For it candidates must produce the following certificates—viz.: 1. Of being not less than twenty-one years of age. 2. Of good moral character. 3. Of having passed one of the following examinations in Arts: (*a*) the examination for graduation in Arts at one of the following universities—Oxford, Cambridge, Durham, Dublin, London, Queen's (Ireland), Edinburgh, Glasgow, St. Andrews, Aberdeen, Calcutta, Madras, Bombay, McGill College (Montreal), Queen's College (Kingston), Victoria (Manchester), and Royal (Ireland); or (*b*) the Preliminary or Extra-professional Examination for graduation in Medicine at one of the following universities—Cambridge, London, Edinburgh, Glasgow, St. Andrews, Aberdeen, Queen's (Ireland), Victoria (Manchester), and Royal (Ireland); or (*c*) the Preliminary Examination in Arts qualifying for the Membership of the Royal College of Physicians of London or for the Fellowship of the Royal College of Surgeons of England; or (*d*) the Preliminary Examination in Arts for the degrees in Medicine of the University of Durham (in 1887, commencing on March 22nd and September 20th). 4. Of attendance on the following course of lectures—viz.: Medicine and Surgery, each two courses of six months; Public Health, one course; Forensic Medicine, Midwifery and Diseases of Women and Children, and Pathology, each one course of three months; Clinical Medical and Clinical Surgical Lectures, each two winters and two summers; Medical Hospital Practice and Surgical Hospital Practice and Post-mortem Demonstrations, each three winters and two summers; Medical Clinical Clerking and Surgical Dressing, each six months; Clinical Obstetrics, three months; attendance on not less than twenty-one cases of Midwifery, and instruction in Vaccination.

N.B.—It is required that one of the four years of professional education shall be spent in attendance at the College of Medicine, Newcastle-on-Tyne. Candidates for the First Examination who have passed the First Examination of the Conjoint Board in England, and candidates who hold a qualification from a recognised Licensing Body in the United Kingdom, will be exempt from the First Examination of the University, except in the subjects of Chemistry, with Physics and Botany. Candidates who have passed the First and Second Examinations of the University will be exempt from the First and Second Examinations of the Conjoint Board.

For the degree of *Master in Surgery* (*M.S.*), the candidate must have passed the examination for the degree of Bachelor in Medicine and must have attended one course of lectures on Operative Surgery. Each candidate will have an additional paper on Surgery and additional clinical and *viva-voce* examinations, and will have to perform operations on the dead body.

For the degree of *Doctor of Medicine* (*M.D.*), candidates must not be less than twenty-four years of age, must have obtained the degree of M.B. at least two years previously, and in the interim have been engaged in medical and surgical practice. Each candidate will be required to write an essay on some medical subject selected by himself and approved by the Professor of Medicine, and to pass an examination thereon.

Candidates for any of the above degrees must give at least twenty-eight days' notice to the registrar of the College.

VICTORIA UNIVERSITY, MANCHESTER.

Colleges of the University: Owens College, Manchester, and University College, Liverpool.

Three degrees in Medicine and Surgery are conferred by the Victoria University—viz., Bachelor of Medicine (M.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.).

All candidates for degrees in Medicine and Surgery are required—(1) To have matriculated in the University; and (2) to pass an examination called the Entrance Examination in Arts, or to have passed such other examination as may be recognised by the University for this purpose.[8]

Degree of Bachelor of Medicine.—Before admission to the degree of M.B. candidates are required to present certificates that they will have attained the age of twenty-one years on the day of graduation, and that they have pursued the courses of study required by the University Regulations during a period of not less than four years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in a College of the University, and one year at least having been passed in a College of the University subsequently to the date of passing the Preliminary Examination in Science. All candidates for the degree of Bachelor of Medicine are required, after matriculating, to satisfy the examiners in the several subjects of the following examinations—the Preliminary Examination in Science, the Intermediate Examination for the degree of M.B., and the Final Examination for the degree of M.B.

The Preliminary Examination in Science.—The subjects of examination are as follows:—1. Chemistry. 2. Elementary Biology. 3. Physics. Candidates for the Preliminary Examination in Science must have attended during at least one year courses, both of lectures and of laboratory work, in each of the above-named subjects.

The Intermediate M.B. Examination.—The subjects of examination are as follows:—1. Anatomy. 2. Physiology (including Physiological Chemistry and Histology). 3. Materia Medica and Pharmacy. Candidates for the Intermediate M.B. Examination are required to have passed the Preliminary Examination in Science and to have attended courses of instruction in Anatomy for one winter session, in Physiology for two winter sessions (but one session will be accepted provided that not less than one hundred class attendances are presented by the candidate), and in Materia Medica and Pharmacy for one summer session. The certificates must show (1) that the human body has been dissected twice at least; (2) that laboratory instruction has been received in Physiology; (3) that practical instruction has been received in Materia Medica and Pharmacy.

The Final M.B. Examination.—The examination is divided into two parts, called the First Part and the Second

[7] This fee will continue to be £10 to all such as, having taken their M.B. degree under the former regulations, shall not have paid the fee of £5 at the Preliminary Scientific Examination.

[8] The Examinations at present recognised are:—1. The Preliminary Examination of the Victoria University provided Latin and Mechanics have been taken up. 2. The Matriculation Examination of the University of London. 3. The Previous Examination of the University of Cambridge. 4. Responsions and Moderations of the University of Oxford. 5. The Leaving Certificate Examination of the Oxford and Cambridge Boards, provided that it include Latin, English, Mathematics, and Elementary Mechanics. 6. The Final Examination for Graduation in Arts of any University in Great Britain and Ireland.

Digitized by Google

Part respectively, which may be passed separately or on the same occasion, but the First Part cannot be taken before the end of the third year, and the Second Part cannot be taken before the end of the fourth year, of medical study in accordance with the University Regulations. The subjects of examination are as follows:— Part I.: 1. Systematic Surgery. 2. Pharmacology and Therapeutics. 3. General Pathology. Part II.: 1. Systematic and Clinical Medicine, including Mental Diseases. 2. Practical and Clinical Surgery. 3. Obstetrics and Diseases of Women and Children. 4. Morbid Anatomy. 5. Forensic Medicine. 6. Hygiene.

Candidates, before presenting themselves for the Final Examination, are required to have passed the Intermediate Examination, and to furnish certificates—1. Of having attended the Medical and Surgical Practice of a hospital or hospitals, approved by the University, during at least three years, of which years two at least must be subsequently to the date of passing the Intermediate Examination, except when exemption has been granted by the General Board of Studies, after report from the Departmental Board of Medical Studies. 2. Of having attended during at least twelve months demonstrations in the post-mortem theatre of a hospital. 3. Of having attended, under proper supervision, at least twenty cases of labour. 4. Of having during at least three months received in either a general or a special hospital, approved by the University, such Clinical Instruction in the Diseases peculiar to Women as shall be approved by the University. 5. Of having acquired proficiency in Vaccination. 6. Of having attended courses of instruction, approved by the University, in a College of the University or in a College or Medical School recognised for this purpose by statute of the University, in the following subjects:—(*a*) Systematic Medicine, (*b*) Clinical Medicine, (*c*) Systematic Surgery, (*d*) Practical Surgery, (*e*) Clinical Surgery, (*f*) Obstetrics and Diseases of Women and Children, (*g*) Pharmacology and Therapeutics, (*h*) General Pathology and Morbid Anatomy, (*i*) Forensic Medicine, (*j*) Hygiene.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously received the degree of Bachelor of Medicine, and at least one year has elapsed since they passed the examination for that degree. Candidates for the degree of Doctor of Medicine are required to present a printed dissertation embodying the results of personal observations or original research, either in some department of medicine or of some science directly relative to medicine. No candidate will be admitted to the degree unless his dissertation, after report from the Departmental Board of Medical Studies, shall have been recommended by the General Board of Studies to the Council for acceptance in that behalf. Candidates may be examined on any subject connected with their dissertations.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously received the degree of Bachelor of Medicine, and at least one year has elapsed since they passed the examination for that degree.

The subjects of examination are as follows: (1) Surgical Anatomy, (2) Surgical Pathology, (3) Practical Surgery, including the performance of operations on the dead body, (4) Clinical Surgery, (5) Ophthalmology.

UNIVERSITY OF EDINBURGH

Three medical degrees are conferred by the University of Edinburgh—namely, Bachelor of Medicine (M.B.), Master in Surgery (C.M.), and Doctor of Medicine (M.D.). The degree of Master in Surgery is not conferred on any person who does not also at the same time obtain the degree of Bachelor of Medicine.

No one is admitted to the degrees of Bachelor of Medicine and Master in Surgery who has not been engaged in medical and surgical study for four years—the medical session of each year, or *annus medicus*, being constituted by at least two courses of not less than one hundred lectures each, or by one such course and two courses of not less than fifty lectures each; with the exception of the clinical courses, in which lectures are to be given at least twice a week during the prescribed periods.[9]

[9] No course of lectures will be allowed to qualify unless the lecturer certifies that it has embraced at least one hundred lectures, or fifty lectures, in conformity with the requirements of this section. Three months' courses on Materia Medica, Pathology, and Midwifery do not qualify.

Every candidate for the degrees of M.B. and M.C. must give sufficient evidence by certificates—(*a*) That he has studied each of the following departments of medical science—namely, Anatomy, Chemistry, Materia Medica, Institutes of Medicine or Physiology, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Children, and General Pathology, each during courses including not less than one hundred lectures; Practical Anatomy, a course of the same duration as those of not less than one hundred lectures;[10] Practical Chemistry, three months; Practical Midwifery, three months at a midwifery hospital, or a certificate of attendance on six cases from a registered medical practitioner; Clinical Medicine, Clinical Surgery,[11] courses of the same duration as those of not less than one hundred lectures, or two courses of three months' lectures, being given at least twice a week; Medical Jurisprudence, Botany, Natural History (including Zoology), during courses including not less than fifty lectures. (*b*) That he has attended, for at least two years, the medical and surgical practice of a general hospital which accommodates not fewer than eighty patients, and possesses a distinct staff of physicians and surgeons. (*c*) That he has attended, during a course of not less than fifty hours' instruction, the class of Practical Materia Medica in the University of Edinburgh, or a similar class conducted in a university or recognised school of medicine, or a similar class conducted by a teacher recognised by the University Court; or that he has been engaged, for at least three months, by apprenticeship or otherwise, in compounding and dispensing drugs at the laboratory of a hospital or dispensary, by a member of a surgical college or faculty, a licentiate of the London or Dublin Society of Apothecaries, or a member of the Pharmaceutical Society of Great Britain. (*d*) That he has attended, for at least six months, by apprenticeship or otherwise, the out-door practice of a hospital, or the practice of a dispensary physician, a surgeon, or a member of the London or Dublin Society of Apothecaries.

Students of Medicine in the London schools, and in the school of the College of Surgeons in Dublin, can obtain there two *anni medici* out of the four required for the Edinburgh degrees in Medicine. One *annus medicus* may be constituted by attendance on Practical Anatomy and Hospital Practice during the winter session. Another *annus medicus* by attending either (*a*) full winter courses on any two of the following subjects—Anatomy, Physiology, Chemistry, Pathology, Surgery, Medicine, Clinical Surgery, Clinical Medicine; or (*b*) on one such course and two three months' courses on any of the following subjects—Botany, Practical Chemistry, Natural History, Medical Jurisprudence. If the student selects the arrangement prescribed in (*a*), attendance on a third course, although unnecessary to constitute an *annus*, will also be accepted. The other subjects and the additional courses, not given in London or Dublin, necessary for the degrees of the University, require to be attended at this University. In provincial schools, where there are no lecturers recognised by the University Court, a candidate can only have one *annus medicus*, and this is constituted by attendance at a qualified hospital along with a course of Practical Anatomy. But in a provincial school where there are two or more lecturers recognised by this University, a second *annus medicus* may be made by attendance on at least two six months', or one six months' and two three months', recognised courses.

Every candidate must deliver, before the 31st day of March of the year in which he proposes to graduate, to the Dean of the Faculty of Medicine a declaration in his own handwriting, that he has completed his twenty-first year, or that he will have done so on or before the day of graduation, and that he will not be, on the day of graduation, under articles of apprenticeship to any surgeon or other master; together with a statement of studies, accompanied with proper certificates.

Each candidate is examined, both in writing and orally, on Chemistry, Botany, and Natural History; on Anatomy, Institutes of Medicine, Materia Medica (including Practical Pharmacy), and Pathology; on Surgery, Practice of Medi-

[10] Certificates of attendance on Practical Anatomy must express not only the number of months engaged in dissection, but the names of the parts dissected, and the degree of care with which the dissections have been made. Students are recommended not to appear for an examination in Anatomy with a view to a degree until they have dissected the human body at least once.

[11] The Medical Faculty recommend that medical students should not attend Clinical Surgery during their first six months' attendance on Clinical Medicine.

Digitized by Google

cine, Midwifery, and Medical Jurisprudence; clinically, on Medicine and on Surgery in a hospital. The examinations on Anatomy, Chemistry, Institutes of Medicine, Botany, Natural History, Materia Medica, and Pathology are conducted, as far as possible, by demonstrations of objects placed before the candidates.

Students who have passed their examination on the first division of these subjects may be admitted to examination on the second division at the end of their third year.

The examination on the third and fourth divisions cannot take place until the candidate has completed his fourth *annus medicus*.

Candidates may, if they choose, be admitted to examination on the first two of these divisions at the end of their third year, or to the fourth examinations at the end of their fourth year.

The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degrees of Bachelor of Medicine and Master in Surgery, and who is of the age of twenty-four years, and produces a certificate of having been engaged, subsequently to his having received the degrees of M.B. and C.M., for at least two years in attendance on a hospital, or in the military or naval medical service, or in medical and surgical practice; provided always that the degree of M.D. shall not be conferred on any person unless he be a graduate in Arts of one of the universities of England, Scotland, or Ireland, or of such other universities as are above specified, or unless he shall, before or at the time of his obtaining the degrees of M.B. and C.M., or thereafter, have passed a satisfactory examination on *three* of the subjects mentioned in Section II. of the statutes relative to preliminary examination. Two of these must be Greek and Logic or Moral Philosophy, and the third is to be one of the following subjects, at the option of the candidate—namely, French, German, Higher Mathematics, and Natural Philosophy; and provided also that the candidate for the degree of M.D. shall submit to the Medical Faculty a thesis, certified by him to have been composed by himself, and which shall be approved by the Faculty, on any branch of knowledge comprised in the professional examinations for the degrees of M.B. and C.M., which he may have made a subject of study after having received that degree.

The fees for M.B. and C.M. are £22. Total fees and stamp for graduating as M.D. only, by regulations for students commencing before February, 1861, £25. The fees for examination must be paid at the secretary's office ten days before the dates thereof, and the fees for the degree of M.D. and the stamp duty for the latter must be paid on or before the 15th day of July in the year of graduation. In the event of the candidate not passing any one of the professional examinations the fee is not returned; but he may appear at one subsequent examination without paying an extra fee, and at any future examination on paying one-half the fee.

UNIVERSITY OF GLASGOW.

Three degrees in Medicine are granted—viz., Bachelor of Medicine, Master in Surgery, and Doctor of Medicine. The curricula of study and the examinations for the several degrees conferred are nearly the same as in the University of Edinburgh. The annual term for conferring medical and surgical degrees is the 1st of August. The Preliminary Examinations of medical students in branches of general education begin on the 6th of October, 1886, and on the 30th of March, 1887.

The fees for the degrees are £21 for M.B. and C.M., which are obtained together, and £15 for M.D.

The regulations under which the above degrees are granted and the notices of the subjects of examination may be obtained by application to the assistant-clerk, Matriculation Office, the University.

After the present winter session the examinations in the first, second, and third groups of subjects of the professional examinations for degrees will be held in July instead of October, as at present.

UNIVERSITY OF ABERDEEN.

The curricula for the several degrees conferred are nearly the same as in the University of Edinburgh.

Professional Examinations will be held twice in each year—namely, in April and July, directly after the close of the winter and summer sessions.

The fees for graduation are the same as in the University of Edinburgh. Matriculation fee, including all dues, for the winter and summer sessions, £1; summer session alone, 10s.

Candidates who commenced their medical studies before November, 1861, are entitled to appear for examination for the degree of M.D. after four years' study, one of which must have been in the University of Aberdeen.

Besides the Royal Infirmary, students have the opportunity of attending the following institutions: Sick Children's Hospital; General Dispensary, and Lying-in and Vaccine Institutions, daily; Royal Lunatic Asylum; Eye Institution, in which is given clinical instruction on the Diseases of the Eye, and on the Application of the Ophthalmoscope for their diagnosis.

Application for further information should be addressed to the Dean of the Medical Faculty.

UNIVERSITY OF ST. ANDREWS.

Two degrees in Medicine are granted—namely, Bachelor of Medicine and Master in Surgery (M.B., C.M.), and Doctor of Medicine (M.D.). The curricula for these degrees, and the regulations under which they are conferred, differ from those of the University of Edinburgh only in the particulars noticed below.

The degree of *Doctor of Medicine* may be conferred by the University of St. Andrews on any registered medical practitioner above the age of forty years whose professional position and experience are such as, in the estimation of the University, to entitle him to that degree, and who shall, on examination, satisfy the medical examiners of the sufficiency of his professional knowledge; provided always that degrees will not be conferred under this section on a greater number than ten in any one year. The examinations are held yearly towards the end of April. Candidates must lodge with the Dean of the Medical Faculty the following certificates, along with application for admission to examination:—1. A certificate of age, being a baptismal certificate or an affidavit of age. 2. Holograph certificates from at least three medical men of acknowledged reputation in the medical profession or in the medical schools, recommending the candidate to the Senatus for the degree, and testifying to his professional skill and position. As only ten can graduate yearly, candidates will be selected whose service and certificates seem to the Medical Faculty to present the highest professional claims, and where these seem equal preference will be given to age and priority of application. 3. A portion of the graduation fee (viz., £10 10s.) shall be forfeited should the candidate fail to appear or to graduate at the time appointed. A satisfactory examination, written and *vivâ-voce*, must be passed in the following departments—viz., Materia Medica and General Therapeutics, Medical Jurisprudence, Practice of Medicine and Pathology, Surgery, Midwifery, and Diseases of Women and Children.

No one will be received as a candidate for the degree of *Bachelor of Medicine and Master in Surgery* unless two years at least of his four years of medical and surgical study shall have been in one or more of the following universities or colleges—viz., the Universities of St. Andrews, Glasgow, Aberdeen, Edinburgh, Oxford, and Cambridge; Trinity College, Dublin; Queen's College, Belfast; Queen's College, Cork; and Queen's College, Galway.

Subject always to the condition here specified, the studies for candidates for the degree of Bachelor of Medicine and Master in Surgery will be under the following regulations. The remaining years of medical and surgical study may be either in one or more of the universities and colleges above specified, or in the hospital schools of London, or in the school of the College of Surgeons of Dublin, or under such private teachers of medicine as may from time to time receive recognition from the University Court. Attendance during at least six winter months on the medical or surgical practice of a general hospital which accommodates at least eighty patients, and during the same period on a course of Practical Anatomy, may be reckoned as one of such remaining years.

Every candidate for examination for the degree of M.B. and C.M. is required to lodge a declaration of age, a statement of his course of study, his inaugural dissertation, and all his certificates with the Dean of the Medical Faculty, on or before the 25th of March in each year.

Digitized by Google

UNIVERSITY OF DUBLIN (TRINITY COLLEGE).

Matriculation.—All students in the School of Physic intending to practise Physic must be matriculated, for which a fee of 5*s.* is payable. No student can be admitted for the winter course after Nov. 25th.

Previous Medical Examination.—Candidates for degrees and licences in Medicine and Surgery are required to pass a previous examination in Physics, Chemistry, Botany, Comparative Anatomy, Descriptive Anatomy, and Institutes of Medicine (Practical Histology and Physiology) previously to their degree examination.

Bachelor in Medicine.—A candidate for this degree must be a graduate in Arts, and may obtain the degree of Bachelor in Medicine at the same Commencements as that at which he receives his degree of B.A., or at any subsequent Commencements. The medical education of a Bachelor in Medicine is of four years' duration, and comprises attendance on a single course of each of the following lectures—Anatomy, Practical Anatomy, Theory of Surgery, Chemistry, Materia Medica and Pharmacy, Physiology, Practice of Medicine, Midwifery, Botany, Medical Jurisprudence, Heat, Electricity, Magnetism, Comparative Anatomy; three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other metropolitan hospital recognised by the Board of Trinity College; six months' instruction in Practical Midwifery, including Clinical Lectures; a certificate of personal attendance on Fever cases, with names and dates of cases. Six months' dissections, three months' laboratory instruction in Chemistry, three months' Practical Histology, and one month's instruction in Vaccination are required. Any of the above-named courses may be attended at any medical school in Dublin recognised by the Provost and Senior Fellows. Fee for the *Liceat ad Examinandum*, £5; for the M.B. degree, £11.

Doctor in Medicine. A Doctor in Medicine must be M.B. of at least three years' standing, or have been qualified to take the degree of M.B. for three years, and must read a thesis or undergo an examination before the Regius Professor of Physic, in accordance with the rules and statutes of the University. Total amount of fees for this degree, £13.

Bachelor in Surgery.—A Bachelor in Surgery must be a Bachelor in Arts and in Medicine, and have spent four years in the study of Surgery and Anatomy. He must also pass a public examination in the Hall before the Professors of the School of Physic, having previously completed the prescribed curriculum of study, which includes the following additions to the courses named above for the M.B.: Operative Surgery, Two Courses of Dissections, Ophthalmic Surgery.[12] Candidates are required to perform surgical operations on the dead subject. Fee for the *Liceat ad Examinandum*, £5; for the degree of Bachelor in Surgery, £5.

Master in Surgery.[13]—A Master in Surgery must be a Bachelor in Surgery of three years' standing, or have been qualified to take the degree of Bachelor in Surgery for three years; and must read a thesis publicly before the Regius Professor of Surgery, or undergo an examination before the Regius Professor, according to regulations to be approved by the Provost and Senior Fellows. Fee for the degree of Master in Surgery, £11.

University Licences. Candidates for the licences in Medicine or Surgery must be matriculated in Medicine, and must have completed two years in Arts and four years in medical studies.

Licentiate in Medicine.—The medical course and examination necessary for the licence in Medicine are the same as for the degree of M.B. Fee for the *Liceat ad Examinandum*, £5; for the licence in Medicine, £5.

Licentiate in Surgery.—The surgical course and examination necessary for the licence in Surgery are the same as for the degree of Bachelor in Surgery. Fee for the *Liceat ad Examinandum*, £5; for the licence in Surgery, £5.

The total cost of the education and first degrees in Medicine and Surgery is as follows, in addition to the fees for education in Arts and B.A. degree (£83 4*s.*); Medical and Surgical Lectures, £60 12*s.* 6*d.*; Hospitals, £44 2*s.*; Medical and Surgical Examinations and Degrees, £26.

[12] Students in the School of Physic who matriculated before June 22nd, 1872, may obtain the degree of Master in Surgery according to the regulations in force previously to the creation of the degree of Bachelor in Surgery.

[13] Masters in Surgery must be of the standing of Master of Arts.

ROYAL UNIVERSITY OF IRELAND.

The following degrees are conferred by the University in this Faculty: Bachelor of Medicine, Doctor of Medicine, Master of Surgery, Master of Obstetrics; in Sanitary Science, a special diploma. All the medical examinations are held twice yearly—viz., towards the end of April and in October.

The course for degrees in Medicine &c. is one of at least four years' duration. Students who have commenced their medical studies since January 1st, 1884, must also produce a certificate of having been registered as students in Medicine by the Medical Council for a period of at least forty-five months. No one can be admitted to any degree in Medicine who is not fully twenty-one years of age. All candidates for these degrees are, in addition to attending the lectures and complying with the other conditions to be from time to time prescribed, required to pass the following examinations: the Matriculation Examination, the First University Examination, the First Examination in Medicine, the Second Examination in Medicine, and the Degree Examination.

The First Examination in Medicine.—Students are admitted to this examination after the lapse of one academical year from the time of their matriculation. The subjects of this examination are—Zoology, Botany, and a modern language (either French or German). Candidates who have passed in a modern language at the First University Examination in Arts are exempt from again presenting this subject at the First Examination in Medicine, except as a qualification for admission to compete for Honours, the answering of the candidates in the three subjects above-mentioned being taken into account in awarding Honours.

The Second Examination in Medicine.—Students are admitted to this examination after the lapse of one academical year from the time of passing the First Examination in Medicine, provided they have completed the First Period of the Course of Medical Studies. The subjects of this examination are—Anatomy, Physiology, Materia Medica (Pharmacology), and Chemistry.

The Examination for the Degree of M.B.—Students are admitted to this examination after the lapse of one academical year from the time of passing the Second Examination in Medicine, provided they have completed the Second Period of the Course of Medical Studies. The subjects of this examination are—Anatomy, including Practical Anatomy; Physiology, including Practical Physiology and Histology; Surgery, Midwifery, and Diseases of Women and Children; Vaccination; Theory and Practice of Medicine, Medical Jurisprudence; Mental Diseases.

M.D. Degree.—Candidates may be admitted to this degree after the lapse of two academical years from the time of obtaining the degree of M.B.; provided, however, that all persons who were students in Medicine in the Queen's University at the date of its dissolution shall be entitled, if they so desire, to obtain the degree of M.D., instead of the degree of M.B., upon passing the examination herein prescribed for the M.B. degree. Every candidate will be examined at the bedside, and required to diagnose at least six cases, medical and surgical, and prescribe treatment, and to write detailed reports on at least two cases to be selected by the examiners, and to discuss all the questions arising thereon. Every candidate must submit to the medical examiners, for their approval, a thesis certified by him (or her) to have been composed by himself (or herself). No thesis will be approved which does not contain some original or personal observations in Practical Medicine, Surgery, Midwifery, or in some of the sciences embraced in the curriculum, or else a full digest and critical exposition of the opinions and researches of others on the subject selected by the candidate, accompanied by precise references to the publications quoted.

The *M.Ch. Degree* will be conferred only on graduates in Medicine of the University. The examination will comprise the Theory and Practice of Surgery, including Operative and Clinical Surgery.

The *M.A.O. Degree* will also be conferred only on graduates in Medicine of the University. The examination will comprise the Theory and Practice of Midwifery, and the use of Obstetrical Instruments and appliances. Candidates will be required to undergo a special written examination in Midwifery, Gynæcology, and Diseases of Children, in addition to the other tests.

Digitized by Google

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

The licence of this College is a qualification to practise Medicine, Surgery, and Midwifery, and is recognised by the Local Government Board as a qualification in Surgery as well as in Medicine.

Licentiates.—Every candidate for the College licence (except when otherwise provided by the bye-laws) is required to produce satisfactory evidence to the following effect:—Of having attained the age of twenty-one years. Of moral character. Of having passed before the commencement of professional study an examination in the subjects of general education recognised by the General Medical Council. Of having been registered as a medical student in a manner prescribed by the General Medical Council. Of having been engaged in professional studies during at least forty-five months, of which at least three winter sessions and two summer sessions shall have been passed at a recognised medical school or schools, and one winter session and two summer sessions in one or other of the following ways:—

1. Attending the practice of a hospital or other institution recognised by the College for that purpose. 2. Receiving instruction as the pupil of a legally qualified practitioner having opportunities of imparting a practical knowledge of Medicine, Surgery, or Midwifery. 3. Attending lectures on any of the required subjects of professional study at a recognised place of instruction. Of having attended, during three winter sessions and two summer sessions, the medical and surgical practice at a recognised hospital or hospitals.[14] Of having discharged the duties of a medical clinical clerk during six months, and of a surgical dresser during other six months; and of having been engaged during six months in the clinical study of Diseases peculiar to Women. Of having received instruction in Chemistry, Practical Chemistry, Materia Medica, and Practical Pharmacy. Of having attended a course of lectures on the following subjects:—Anatomy (with dissections), during twelve months; Physiology; a practical course of General Anatomy during a winter or a summer session, consisting of not less than thirty meetings of the class; Pathological Anatomy; Principles and Practice of Medicine; Principles and Practice of Surgery; Midwifery and the Diseases peculiar to Women; Forensic Medicine. Of having attended Clinical Lectures on Medicine during nine months, and also Clinical Lectures on Surgery during nine months, and of having been engaged during a period of three months in the Clinical Study of Diseases peculiar to Women. Of having passed the professional examinations, of which there are three, each partly written, partly oral, and partly practical. The subjects of the first examination are:—Chemistry, including Chemical Physics—viz., Heat, Light, and Electricity; Materia Medica and Pharmacy; and Osteology. The subjects of the second examination are Anatomy and Physiology. The subjects of the final examination are Medical Anatomy and Pathology, including Morbid Anatomy; the Principles and Practice of Medicine; Surgical Anatomy and Pathology, including Morbid Anatomy; the Principles and Practice of Surgery; Midwifery and Diseases peculiar to Women; Forensic Medicine; Public Health and Therapeutics.

Any candidate who shall produce satisfactory evidence of having passed an examination on Anatomy and Physiology, conducted by a university in the United Kingdom, in India, or in a British colony, or by the College of Surgeons in England, Scotland, or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, shall be exempt from re-examination on those subjects. Any candidate who shall produce satisfactory evidence of having passed an examination on Chemistry and Materia Medica, required for a degree in Medicine at a university in the United Kingdom, in India, or in a British colony, will be exempted from re-examination on those subjects. Any candidate who shall have obtained a degree in Surgery at a university in the United Kingdom, after a course of study and an examination satisfactory to the College, shall be exempt from re-examination on Surgical Anatomy and on the Principles and Practice of Surgery. Any candidate who shall have passed the examination on Surgery conducted by the Royal College of Surgeons of England, or the Royal College of Surgeons of Edinburgh, or the Royal College of Surgeons in Ireland, or the Faculty of Physicians and Surgeons of Glasgow, after a course of study and an examination satisfactory to the College, shall be exempt from re-examination on Surgical Anatomy and on the Principles and Practice of Surgery.

[14] A three months' course of clinical instruction in the wards of a recognised lunatic hospital or asylum may be substituted for the same period of attendance in the medical wards of a general hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

REGULATIONS RESPECTING THE EDUCATION AND EXAMINATIONS APPLICABLE TO CANDIDATES FOR THE DIPLOMA OF MEMBER OF THE COLLEGE.

Professional Education.—The following are recognised modes of commencing professional education:—(1) Attendance on the practice of a hospital, or other public institution recognised by this College for that purpose. (2) Instruction as the pupil of a legally qualified surgeon, holding the appointment of surgeon to a hospital, general dispensary, or union workhouse, or where such opportunities of practical instruction are afforded as shall be satisfactory to the Council. (3) Attendance on lectures on Anatomy, Physiology, or Chemistry, by lecturers recognised by this College.

Candidates, prior to their admission to the First or Primary Examination on Anatomy and Physiology, will be required to produce the following certificates, viz.:—Of having, prior to the commencement of professional study, been registered by the General Medical Council. Of having attended lectures on Anatomy during two winter sessions. Of having performed dissections during not less than two winter sessions. Of having attended lectures on General Anatomy and Physiology[15] during one winter session. Of having attended a practical course of General Anatomy and Physiology[16] during another winter or a summer session, consisting of not less than thirty meetings of the class.

Candidates who commenced their professional studies on or after October 1st, 1882, and shall have pursued those studies in recognised medical schools in England, will be required, before presenting themselves for the Primary or Anatomical and Physiological Examination for the diploma of Member of the College, to produce certificates of having passed an examination in Elementary Anatomy and Physiology, such examination to be conducted by their teachers at the several medical schools. (1) The periods at which the examination shall be held will be determined by the teachers at the several medical schools, provided that an interval of not less than six months shall elapse between the date at which the candidates shall have passed the examination and the date of their presenting themselves for the Primary Examination at the College. (2) It shall be left to the teachers at the several medical schools to determine the nature and extent of the examination in Elementary Anatomy and Physiology.

Candidates, prior to their admission to the Second or Pass Examination on Surgical Anatomy and the Principles and Practices of Surgery, Medicine, and Midwifery, will be required to produce the following certificates—viz.: Of being twenty-one years of age. Of having been engaged, subsequently to the date of registration by the General Medical Council, during four years, or during a period extending over not less than four winter and four summer sessions, in the acquirement of professional knowledge. Of having attended lectures on surgery during one winter session. Of having attended a course of Practical Surgery during a period occupying not less than six months prior or subsequent to the course required by the preceding Clause 3.[17] Of having attended one course of lectures on each of the following subjects — viz.: Chemistry,[18] Materia Medica, Medicine,

[15] By the Practical Course referred to in Clause 5, it is meant that the learners themselves shall, individually, be engaged in the necessary experiments, manipulations, &c.; but it is not hereby intended that the learners shall perform vivisections.

[16] The certificates of attendance on the several courses of lectures must include evidence that the student has attended the practical instructions and examinations of his teacher in each course.

[17] The course of Practical Surgery referred to in Clause 4 is intended to embrace instruction in which each pupil shall be exercised in practical details, such as in the application of anatomical facts to surgery, on the living person or on the dead body; the methods of proceeding and the manipulations necessary in order to detect the effects of diseases and accidents on the living person or on the dead body; the performance, where practicable, of the operations of surgery on the dead body; the use of surgical apparatus; the examination of diseased structures as illustrated in the contents of a museum of morbid anatomy and otherwise.

[18] The course of lectures on Chemistry included in Clause 5 will not be required in the case of a candidate who shall have passed a satisfactory examination in this subject in his preliminary examination.

Digitized by Google

Forensic Medicine, Midwifery (with practical instruction), and a certificate of having personally conducted not less than ten labours, and Pathological Anatomy during not less than three months. Of having studied Practical Pharmacy during three months. Of having attended a three months' course of Practical Chemistry (with manipulations), in its application to medical study.[19] Of instruction and proficiency in the practice of Vaccination.[20] Of having attended, at a recognised hospital or hospitals, the Practice of Surgery, during three winter[21] and two summer[22] sessions. Of having been individually engaged, at least twice in each week, in the observation and examination of patients at a recognised hospital or hospitals, under the direction of a recognised teacher, during not less than three months.[23] Of having, subsequently to the first winter session of attendance on Surgical Hospital Practice, attended at a recognised hospital or hospitals, Clinical Lectures on Surgery, during two winter and two summer sessions. Of having been a dresser at a recognised hospital, or of having, subsequently to the completion of one year's professional education, taken charge of patients under the superintendence of a surgeon during not less than six months, at a hospital, general dispensary, or parochial or union infirmary recognised for this purpose, or in such other similar manner as, in the opinion of the Council, shall afford sufficient opportunity for the acquirement of Practical Surgery. Of having attended during the whole period of attendance on Surgical Hospital Practice (see Clause 9) demonstrations in the post-mortem rooms of a recognised hospital. Of having attended, at a recognised hospital or hospitals, the Practice of Medicine, and Clinical Lectures on Medicine, during one winter and one summer session.

Special Notice.—Candidates commencing their professional education on or after the 1st of October, 1882, will not be admitted to the Second or Pass Examination until after the expiration of two years from the date of their passing the Primary or Anatomical and Physiological Examination for such diploma, except in the following cases:—When a candidate, before presenting himself for the Primary Examination, shall possess a recognised degree or diploma in Medicine or Surgery, or shall have completed the curriculum of professional education for the diploma. In the case of a candidate who, being desirous of obtaining the Fellowship, shall fail to present himself for the Primary Examination for the Membership at the end of his second year of professional study, but who shall pass at the end of his third winter session the Primary Examination for the Fellowship, it being required in such case that not less than one year of attendance on the Surgical Practice of a recognised hospital shall intervene between the date of his passing the Primary Examination for the Fellowship and the date of his presenting himself for the Second or Pass Examination for the diploma of Member. In the case of a candidate who, having commenced his professional studies by attendance on the practice of a recognised provincial or colonial hospital, and having completed a year of such attendance, shall fail to pass the Primary Examination at the end of his second winter session of attendance at a recognised medical school, provided that in his case not less than one year shall elapse between the date of his passing the Primary Examination and the date of his presenting himself for the Second or Pass Examination for the diploma of Member. When a candidate, owing to illness, duly certified by one or more of the teachers of his medical school, shall be prevented from presenting himself for the Primary Examination on the completion of his second year of professional study. And in the case of a candidate who, from some unforeseen circumstances, shall fail to present himself for the Primary Examination on the completion of his second year of professional study, it being left to the Court of Examiners to determine whether in such case the candidate shall or shall not be required to comply with the regulation.

Certificates of attendance upon the practice of a recognised provincial or colonial hospital unconnected with, or not in convenient proximity to, a recognised medical school will not be received for more than one winter and one summer session of the hospital attendance required by the regulations of this College. Those candidates who shall have pursued the whole of their studies in Scotland or Ireland will be admitted to examination upon the production of the several certificates required respectively by the College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, and the College of Surgeons in Ireland from candidates for their diploma, together with a certificate of instruction and proficiency in the practice of Vaccination, and satisfactory evidence of having been occupied subsequently to the date of registration by the General Medical Council, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge; and in the case of candidates who shall have pursued the whole of their studies at recognised foreign or colonial universities, upon the production of the several certificates required for their degree by the authorities of such universities, together with a certificate of instruction and proficiency in the practice of Vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the Preliminary Examination, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge.

Professional Examination.—This examination is divided into two parts. The First or Primary Examination, on Anatomy and Physiology, is partly written and partly demonstrative on the recently dissected subject, and on prepared parts of the human body. The Second or Pass Examination, on Surgical Anatomy and the Principles and Practice of Surgery, Medicine, and Midwifery,[24] is partly written, partly oral, and partly on the practical use of surgical apparatus and the practical examination of patients.

The Primary Examinations are held in the months of January, April, May, July, and October, and the Pass Examinations in the months of January, April, July, and October. Candidates will not be admitted to the Primary Examination until after the termination of the second winter session of their attendance at a recognised school or schools; nor to the Pass or Surgical Examination until after the termination of the fourth year of their professional education. The fee of £5 5*s.*, paid prior to the first admission to the Primary Examination, is retained whether the candidate pass or fail to pass the examination, but is allowed as part of the whole fee of £22[25] payable for the diploma. A candidate, after failure at any Primary Examination, is required, on admission to any subsequent Primary Examination, to pay a further fee of £3 3*s.*, which is retained, whether he pass or fail to pass the examination, and which further fee is not allowed as part of the whole fee of £22 for diploma.

The fee of £16 15*s.* is payable prior to each admission to the Pass Examination; but on each occasion of failure the balance of £11 10*s.* is returned to the candidate. A candidate, having entered his name for either the Primary or Pass Examination, who shall fail to attend, will not be allowed to present himself for examination within the period of three months from the date at which he shall have failed so to attend. A candidate referrred on the Pass Examination is required, unless the Court of Examiners shall otherwise determine, to produce, prior to his admission to re-examination, a certificate of at least six months' further attendance on the surgical practice of a recognised hospital, together with lectures on clinical surgery, subsequently to the date of his reference.

[19] The certificates of attendance on the several courses of lectures must include evidence that the student has attended the practical instructions and examinations of his teacher in each course.

[20] The certificate of instruction in vaccination must be such as will qualify its holder to contract as a Public Vaccinator under the Regulations at the time in force of the Local Government Board.

[21] The winter session comprises a period of six months, and, in England, commences on the 1st of October and terminates on the 31st of March.

[22] The summer session comprises a period of three months, and, in England, commences on the 1st of May and terminates on the 31st of July.

[23] It is intended that the candidate should receive the instruction required by Clause 10 at an early period of his attendance at the hospital.

[24] Candidates can claim exemption from examination in Medicine and Midwifery under the following conditions—viz: The production by the candidate of a degree, diploma, or licence in Medicine and Midwifery entitling him to register under the Medical Act of 1858, or a degree, diploma, or licence in Medicine and Midwifery of a colonial or foreign university approved by the Council of the College. A declaration by the candidate, prior to his admission to the Pass Examination, that it is his intention to obtain either of the qualifications in Medicine and Midwifery mentioned in the foregoing paragraph, in which case the diploma of the College will not be issued to him until he shall produce either the said qualification, or proof of having passed the several examinations entitling him to receive the same.

[25] This sum of £22 is exclusive of the fee of £2 paid for the Preliminary Examination.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Regulations relating to the several Examinations applicable to Candidates who commenced their Professional Education on or after the 1st of October, 1884.

Any candidate who desires to obtain both the licence of the Royal College of Physicians of London and the diploma of Member of the Royal College of Surgeons of England is required to comply with the following regulations, and to pass the examinations hereinafter set forth. Every such candidate who shall commence professional study on or after Oct. 1st, 1884, will be required, at the times prescribed for the respective examinations, to produce satisfactory evidence—1. Of having been registered as a medical student by the General Medical Council. 2. Of having been engaged in professional studies at least forty-five months, during which not less than three winter sessions and two summer sessions shall have been passed at one or more of the Medical Schools recognised by the two Colleges. 3. Of having received instruction in the following subjects: (*a*) Chemistry, including Chemical Physics, meaning thereby Heat, Light, and Electricity; (*b*) Practical Chemistry; (*c*) Materia Medica; (*d*) Pharmacy. 4. Of having performed Dissections at a recognised medical school during not less than twelve months. 5. Of having attended, at a recognised medical school—(*a*) A course of lectures on Anatomy during not less than six months, or one winter session; (*b*) a course of lectures on General Anatomy and Physiology during not less than six months, or one winter session; (*c*) a separate practical course of General Anatomy and Physiology during not less than three months. 6. Of having attended at a recognised medical school—(*a*) a course of lectures on Medicine during not less than six months, or one winter session; (*b*) a course of lectures on Surgery during not less than six months, or one winter session; (*c*) a course of lectures on Midwifery and Diseases peculiar to Women during not less than three months; (*d*) systematic practical instruction in Medicine, Surgery, and Midwifery; (*e*) a course of lectures on Pathological Anatomy during not less than three months; (*f*) demonstrations in the post-mortem room during the whole period of attendance on clinical lectures; (*g*) a course of lectures on Forensic Medicine during not less than three months. 7. Of having attended, at a recognised hospital or hospitals, the practice of Medicine and Surgery during three winter and two summer sessions. 8. Of having attended at a recognised hospital or hospitals during nine months Clinical Lectures on Medicine, and during nine months Clinical Lectures on Surgery, and of having been engaged during a period of three months in the Clinical Study of Diseases peculiar to Women. 9. Of having discharged, after he has passed the Second Examination, the duties of a Medical Clinical Clerk during six months, and of a Surgical Dresser during other six months. 10. Of having received instruction in the practice of Vaccination.

Professional Examinations.—There are three Professional Examinations, called herein the First Examination, the Second Examination, and the Third or Final Examination, each being partly written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and October, unless otherwise appointed. Every candidate intending to present himself for examination is required to give notice in writing to the registrar of the Royal College of Physicians, or to the secretary of the Royal College of Surgeons, fourteen clear days before the day on which the examination commences, transmitting at the same time the required certificates.

The subjects of the First Examination are—Chemistry, Chemical Physics, Materia Medica, Pharmacy, Elementary Anatomy, and Elementary Physiology. A candidate may take this examination in three parts at different times, or he may present himself for the whole at one time. A candidate will be admitted to the examination on Chemistry and Chemical Physics, Materia Medica, and Pharmacy, on producing evidence of having been registered as a medical student by the General Medical Council, and of having received instruction in Chemistry, Materia Medica, and Pharmacy; but he will not be admitted to the examination on Elementary Anatomy and Elementary Physiology earlier than the end of his first winter session at a medical school. A candidate rejected in one part or more of the First Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and he will be re-examined in the subject or subjects in which he has been rejected.

The fees for admission to the First Examination are as follows: for the whole examination, £10 10*s.*; for re-examination after rejection in either of the parts, £3 3*s.*

The subjects of the Second Examination are: Anatomy and Physiology. A candidate may present himself for examination in either of these subjects or parts separately, or in both at one time. A candidate will be admitted to the Second Examination after the lapse of not less than six months from the date of his passing the first examination, on producing evidence of having completed, subsequently to registration as a medical student, eighteen months of professional study at a recognised medical school or schools, and of having complied with the regulations prescribed in Section I., Clauses 4 and 5. A candidate rejected in either part or in both parts of the second examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and will be re-examined in the subject or subjects in which he has been rejected.

The fees for admission to the second examination are as follows: for the whole examination, £10 10*s.*; for re-examination after rejection in either of the two parts, £3 3*s.*

The subjects of the final examination are: Medicine, including Therapeutics, Medical Anatomy, and Pathology; Surgery, including Surgical Anatomy, and Pathology; Midwifery, and Diseases peculiar to Women. A candidate may present himself for examination in these three subjects or parts separately or at one time. A candidate will be admitted to the third or final examination on producing evidence:—1. Of being twenty-one years of age. 2. Of having passed the second examination. 3. Of having studied Medicine, Surgery, and Midwifery, in accordance with the regulations prescribed in Section I., Clauses 2 and 6 to 10. The Colleges do not admit to either part of the Third or Final Examination any candidate (not exempted from registration) whose name has not been entered in the Medical Students' Register at least forty-five months, nor till the expiration of two years after his having passed the Second Examination. A candidate rejected in the Third or Final Examination, or in one or more of the three parts into which he may have divided it, will not be admitted to re-examination until after the lapse of a period of not less than six months from the date of rejection, and he will be re-examined in the subject or subjects in which he previously failed to pass. Any candidate who shall have obtained a colonial, Indian, or foreign qualification which entitles him to practise Medicine or Surgery in the country where such qualification has been conferred, after a course of study and examination equivalent to those required by the Regulations of the two Colleges, shall, on production of satisfactory evidence as to age and proficiency in Vaccination, be admissible to the Second and Third Examinations.

The Fees for admission to the Third or Final Examination are as follows: for the whole Examination, £15 15*s.*; for re-examination after rejection in Medicine, £5 5*s.*; for re-examination after rejection in Surgery, £5 5*s*; for re-examination after rejection in Midwifery, £3 3*s.*

THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH, AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

The above Colleges and Faculty have made arrangements by which, after one series of examinations, held in Edinburgh or in Glasgow, the student may obtain the diplomas of the three co-operating bodies. The general principle of this joint examination is that it shall be conducted by a board in which each body is represented in those branches which are common to both Medicine and Surgery, but that the College of Physicians shall take exclusive charge of the examination in Medicine, and the College of Surgeons, along with the Faculty of Physicians and Surgeons of Glasgow, of the examination in Surgery.

The three co-operating bodies grant their Single Qualifications only to candidates who are already registered as possessing another and opposite qualification in Medicine or Surgery, as the case may be. The Royal College of Physicians of Edinburgh may, notwithstanding this agreement, grant its licence on examination to candidates already possessed

Digitized by Google

of one or other of the surgical qualifications mentioned in Schedule A of the Medical Act, 1858; and the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow, may each grant its licence on examination to candidates, already Licentiates of one of the Colleges of Physicians of the United Kingdom, or Graduates in Medicine of a British or Irish University. Copies of the Regulations for the Single Qualification of any of the bodies may be had on application to the respective secretaries.

Professional Education.—Candidates must have been engaged in professional study during forty-five months after passing the examination in General Education,[26] which period will include not less than four winter sessions' or three winter and two summer sessions' attendance at a recognised medical school. At the meeting of the General Medical Council, in May, 1885, it was recommended that hereafter the duration of study should be five years.

The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinct courses of lectures: Anatomy, Practical Anatomy, Chemistry, Practical or Analytical Chemistry, Materia Medica, Physiology, Practice of Medicine, Clinical Medicine, Principles and Practice of Surgery, Clinical Surgery, Midwifery and the Diseases of Women and Children, Medical Jurisprudence, Pathological Anatomy. The six months' courses delivered in Scotland, with the exception of Clinical Medicine and Clinical Surgery, must consist of not fewer than 100 lectures. The three months' courses must consist of not fewer than 50 lectures. The candidate must also produce the following certificates: (*a*) Of having attended Six Cases of Labour under the superintendence of the practitioner who signs the certificate, who must be a registered medical practitioner. (*b*) Of having attended for three months' instruction in Practical Pharmacy, the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of a class of Practical Pharmacy. (*c*) Of having attended for twenty-four months the practice of a public general hospital containing, on an average, at least eighty patients. (*d*) Of having attended for six months (or three months with three months' hospital clerkship), the practice of a public dispensary specially recognised by any of the co-operating bodies; or of having been engaged for six months as visiting assistant to a registered practitioner. (*e*) Of having been instructed by a registered medical practitioner in the Theory and Practice of Vaccination. Candidates shall be subjected to three Professional Examinationer, herein called the First Examination, the Second Examination, and the Final Examination, to be conducted at separate times, partly in writing and partly practically and orally.

The First Examination will embrace Chemistry, Practical Chemistry, Elementary Anatomy, and Histology, and will take place not sooner than the end of the first year, including a winter and a summer session. The sum of £5 5*s.* must be paid to the Inspector of Certificates for this examination, not later than 11 A.M. of the Saturday preceding it. This sum will be considered as paid to account of the entire fee of £26 5*s.* payable for the three diplomas. In the case of a candidate being unsuccessful at this examination, he will be readmitted to examination after a prescribed interval on payment of £3 3*s.* if he has failed in all subjects, and £3 2*s.* if he has passed in one or more subjects.

The Second Examination will embrace Anatomy, Physiology, Materia Medica and Pharmacy, and will not take place before the termination of the summer session of the second year of study, including two winter and two summer sessions. The sum of £5 5*s.* must be paid to the Inspector of Certificates for this examination, not later than one week before the day of examination. In case of failure, the candidate will be readmitted to examination after the expiration of the prescribed period on payment of £3 3*s.* if he has failed in all subjects, and £2 2*s.* if he has passed in one or more subjects.

The Final Examination will embrace the Principles and Practice of Medicine (including Therapeutics, Medical Anatomy and Pathology), Clinical Medicine, the Principles and Practice of Surgery (including Surgical Anatomy, Operative Surgery and Surgical Pathology), Clinical Surgery, Midwifery (including Gynæcology), Medical Jurisprudence, and Hygiene, and it will not take place before the termination of the full period of study. Every candidate must produce to the inspector, Mr. James Robertson, solicitor, 4, Lindsay-place (George IV. Bridge), Edinburgh, or to Mr. Alexander Duncan, Faculty Hall, 242, St. Vincent-street, Glasgow—(1) satisfactory evidence of his having attained the age of twenty-one years; (2) a certificate of his registration in the books of the General Medical Council (see Chap. IV.); (3) the certificates of the classes above enumerated. Of the fee payable for this examination, which is £15 15*s.*, £5 5*s.* must be paid to the inspector not later than one week prior to the examination day, after which no candidate will be entered. The balance of £10 10*s.* must be paid before the candidate is admitted a licentiate of the co-operating bodies. In case of a candidate being unsuccessful at the Final Examination, he will be readmitted to examination after the expiration of the prescribed period, on payment of £5 5*s.*

[26] See the Laws relating to Registration.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

Examinations in the subjects of the First Professional Examination are held quarterly, in January, April, July, and October. Examinations in the subjects of the Final Examination for the licences in Medicine and in Midwifery of the College are held in the week following the first Friday in each month, except August and September. Every candidate for a licence must return his name to the registrar of the College, and lodge with him his certificates, bank (Royal Bank of Ireland) receipt of fees, and his schedule, at least four days before the first Friday in each month.

Licence in Medicine.—Every candidate for the licence of the College to practise Medicine must produce satisfactory evidence—1. Of character, from a Fellow of the College, or from two registered practitioners. 2. Of having passed an examination in general education, held by some one of the examining bodies recognised by the General Medical Council. 3. Of having been engaged during a period of four years in the study of Medicine. 4. Of having attended courses of lectures on the following subjects, at schools recognised by the College: Practical Anatomy, two courses; Physiology or Institutes of Medicine, Chemistry, Practical Chemistry, Materia Medica, Medical Jurisprudence, Practice of Medicine and Pathology, Surgery, and Midwifery—of each one course. 5. Of having attended for twenty-seven months a recognised medico-chirurgical hospital, in which clinical lectures and clinical instruction in Medicine are given, the attendance not to be for more than nine months in any one year—viz., six winter and three summer months. 6. Of having discharged the duties of Medical Clinical Clerk during six months, or of having taken notes, to the satisfaction of the physician in charge of the case, and certified under his hand, of at least six separate medical cases—including different varieties of acute and chronic diseases—in the wards of a recognised hospital; and of having attended, during the whole period of his attendance on hospital practice, Demonstrations in the post-mortem room of a recognised hospital. (This rule to be enforced in the case of all candidates who shall have commenced their professional studies after Sept. 30th, 1883.) 7. Of having studied Fever for not less than three months in a recognised clinical hospital, containing fever wards, and recorded from daily personal observation at least five cases of fever, to the satisfaction of the attending clinical physician, as attested by his signature. The word "Fever" to include the following diseases only—viz., Typhus, Typhoid, Enteric, and Scarlet Fever, Small-pox, Measles.[27] 8. Of having attended Practical Midwifery and Diseases of Women for six months at a lying-in hospital or maternity recognised by the College, or, where such hospital attendance cannot have been obtained during the course of study, of having been engaged in Practical Midwifery under the supervision of a registered practitioner holding public appointments; in either case not less than twenty labour cases must have been actually attended. 9 Of having been engaged in the practical study of Vaccination. 10. Of having lodged the admission fee in the Royal Bank of Ireland, Foster-place, Dublin, to the credit of the College.

[27] Candidates who commenced their hospital studies between September, 1878, and October, 1879, will be required to conform to Rule 6, or to produce evidence of having attended for nine months a hospital which contained fever wards.

Digitized by Google

The professional examination is divided into two parts: 1. Anatomy, Physiology and Practical Histology, Chemistry, and Materia Medica. 2. Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics. Candidates may be examined in the subjects of the first part at the termination of the second year of study, on producing the certificates in the subjects, or in all the subjects of their education, on the completion of their medical studies. No candidate can be examined in the subjects of the first and second parts in the same month.

Candidates qualified as follows are required to undergo the second part only of the professional examination—viz.: (1) Graduates in Medicine of any university in the United Kingdom, or of any foreign university approved by the College; (2) Fellows, Members, or Licentiates of the Royal Colleges of Physicians of London or Edinburgh; (3) Graduates or Licentiates in Surgery; (4) Candidates who, having completed the curriculum laid down above, shall have passed the previous professional examination or examinations (where there are more than one) of any of the licensing medical authorities in the United Kingdom.

The Membership.—Members of the college alone are eligible to the Fellowship. Every candidate for the membership is required to produce satisfactory evidence:—1. Of having attained the age of twenty-five years. 2. Of being a licentiate of this college for three years at least; or a licentiate of one year's standing who shall be a graduate of Arts of a university in the United Kingdom at the time of his obtaining the licence; or a licentiate of one year's standing, who shall be a registered practitioner of seven years' standing at the time of his obtaining the licence. 3. Of professional conduct and moral character, as testified by a Fellow or Member of the college, or by a Fellow of the Royal College of Physicians of London or of Edinburgh. 4. Of not being engaged in trade; of not dispensing medicine, or making any engagement with a chemist, or any other person, for the supply of medicines; and of not practising medicine or surgery in partnership by deed or otherwise. 5. Of having held, during at least six months, the office of resident physician, or resident medical pupil, in a hospital recognised by the college; or of having acted for the same period as clinical clerk in the medical wards of such hospital; or of having been in medical charge, for at least twelve months, of any public institution for the treatment of the sick. 6. Of having lodged the admission fee of 20 guineas in the Royal Bank of Ireland to the credit of the college.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

Candidates for the Letters Testimonial of the College may present themselves either at a Stated or a Special Examination, as hereinafter set forth. Stated Examinations are held in the months of April, July, and November, commencing on dates of which due notice will be given beforehand by the Council of the College. Candidates *cannot be admitted to these examinations unless they be registered pupils.* They will be divided into two classes—junior and senior.

The junior class must produce certificates of—(*a*) having passed a Preliminary Examination recognised by the General Medical Council (into the curriculum of which the Greek language enters as a compulsory subject), and having attended the following lectures: (*b*) three courses of lectures on Anatomy and Physiology; (*c*) three courses of lectures on Practical Anatomy, with dissections; (*d*) two courses of lectures on Chemistry; (*e*) one course of lectures on Materia Medica; (*f*) one course of lectures on Botany; and (*g*) one course of lectures on Forensic Medicine. This class will be examined in Anatomy, Histology, Physiology, Materia Medica, and Chemistry. The fee for this examination is £5 5*s.* (in addition to the registration fee of £5 5*s.*).

The senior class must produce certificates of having attended the following lectures:—(*a*) Three courses of lectures on the Theory and Practice of Surgery; (*b*) one course of lectures on the Practice of Medicine; (*c*) one course of lectures on Midwifery; also certificates of attendance on (*d*) a recognised hospital for three winter and three summer sessions; (*e*) of instruction in Clinical Ophthalmology, three months, and of attendance for one month at the Cowpock Institution or some other institution approved of by the Council, or under the instruction of a public vaccinator specially recognised by this College for that purpose. This class will be examined in Surgery, Operative Surgery on the subject, and Surgical Appliances, Practice of Medicine, Medical Jurisprudence, and Prescriptions. Each of these examinations will be partly written, partly *viva voce*, and partly practical. The fee for the senior class examination is £15 15*s.*, returnable to the candidate in case of rejection, or to be allowed to him in case he presents himself a second time for the same examination. A further fee of £1 1*s.* is to be paid to the registrar.

THE SOCIETY OF APOTHECARIES, LONDON.

EVERY student purposing to study medicine must previously pass a public examination in Arts recognised by the Medical Council, before proceeding with his medical course. Such examination is held in the Hall of the Society four times a year, in March, June, September, and December, and is conducted by means of printed papers. Candidates will be examined in the English and Latin languages, Mathematics, Elementary Mechanics, and one of the following subjects at the option of the candidate—Greek, French, German, Logic, Botany, and Elementary Chemistry. The subjects may be passed at one or more examinations, and no re-examination is required in any subject passed. Registered medical students may present themselves for examination in special subjects if desired. A form of notice accompanying the regulations, obtained from the Society, has to be filled in by the candidate and sent with the fee (one guinea) fourteen days before the examination. Lists of successful candidates are published.

For a licence to practise every candidate will be required to pass two examinations, named respectively the Primary and the Final, each partly written, partly oral, and partly practical. The Primary is held on the first Wednesday and following day of every month. The Final is divided into two parts; Part I. is held on the second and fourth Wednesday and following day of every month; Part II. is held on every Wednesday and Thursday. The course of medical study required for a licence must occupy four years, of which not less than three winter and two summer sessions must be passed at a recognised hospital or school of medicine.

Every candidate intending to offer himself for examination must pay a fee of £6 6*s.*, which in the event of failure will be retained, but no extra fee is required on re-examination. He must also give seven days' notice, and produce the following certificates: (1) for the Primary Examination, a certificate of the commencement of attendance on lectures, and of the course of medical study pursued; (2) for the Final Examination, a certificate of having completed four years' medical study in conformity with the curriculum prescribed, of moral character, and of having attained the age of twenty-one. On such certificates being found correct a card of admission to the examination will be sent, stating the time of attendance. No unsuccessful candidate can be re-examined until the expiration of three months after the Primary and the first part of the Final Examinations respectively, and of six months after the second part.

Every candidate, before he can be qualified for the Primary Examination must have gone through a course of medical study in Chemistry, General and Practical; Botany; Materia Medica: Practical Pharmacy and Dispensing; Anatomy and Physiology, including Dissections and Demonstrations; and Histology, with Demonstrations. The above, including Prescriptions, Practical Chemistry in the Laboratory, and an examination on the living body, form the several subjects of examination for the Primary, which examination may be passed after the second winter session.

For the Final Examination the candidate must give evidence, before he can present himself, that he has gone through the following course of medical study:—Hospital Practice, Surgical and Medical, with Post-mortem Examinations; Principles and Practice of Surgery; Practical Surgery; Clinical Surgical Lectures; Surgical Clinical Clerk or Dresser; Principles and Practice of Medicine; Clinical Medical Lectures; Medical Clinical Clerk; Pathology; Forensic Medicine and Toxicology; Hygiene (its principles and application); Psychological Medicine; Midwifery and Diseases peculiar to Women and Children; Clinical Instruction in the same; attendance on not less than twenty Midwifery cases; and Practical Vaccination.

The Final Examination, which cannot be passed till after the completion of the medical course, and the expiration of forty-five months from registration as medical student, embraces the above; and, in addition, in Part I., Surgical Anatomy,

Digitized by Google

Surgical Pathology, Surgical instruments and appliances, with a clinical examination of Surgical cases; in Part. II., Obstetric instruments and appliances, Microscopic examinations of morbid structure, and a clinical examination of medical cases. Part I. must precede Part II., and Part II. may be passed any time after Part I.

A candidate who has previously passed either a medical or surgical examination at one of the Medical Colleges or Universities of the United Kingdom is in some cases exempt from certain portions of the examination for the Certificate of Licentiate of this Society. In the case of Graduates of Colonial and Foreign Colleges and Universities, such examinations will be duly considered on their respective merits.

The Society give annually prizes for proficiency in Botany, in Materia Medica, and in Pharmaceutical Chemistry to registered medical students who compete and come up to the required standard, but no student is allowed to present himself for such examination until the end of the third year of his medical studies. Two examinations are held for this purpose in the month of June: the first on the third Thursday, at the Hall of the Society, chiefly written; the second, practical, on the following Saturday in the "Physic Garden" at Chelsea. A written notice must be sent to the Bedell before the 1st of June, which notice must be accompanied by evidence of registration and of attendance on their medical studies. The prizes consist of a gold medal, to be awarded to the candidate who distinguishes himself the most in the examination; and of a silver medal and a book, or books, to the candidate who does so in the next degree.

The examination of candidates for a certificate to act as an assistant in compounding and dispensing medicines, will be as follows:—In Translating Prescriptions; in the British Pharmacopœia; in Pharmacy, Pharmaceutical Chemistry, Materia Medica, and Medical Botany. Such examination is held every Thursday in the Hall; seven days' notice must be given, and a fee of two guineas paid, which in the event of failure is retained, no further payment being required for re-examination, before which is allowed three months must have elapsed.

Tickets of admission to the Society's Botanic Gardens at Chelsea, and to the Lectures on Botany when there given, can be had on application at the Hall of the Society.

APOTHECARIES' HALL OF IRELAND.

The Professional Education.—Every candidate for the licence to practise Medicine and Pharmacy must produce certificates to the following effect:—Of having passed a preliminary examination in Arts recognised by the General Medical Council previously to entering on professional study. Of registration in the Medical Students' Register. Of medical study, after registrations of at least five years. The course of medical study after registration should occupy at least five years, if the subjects of Elementary Physics, Chemistry, and Biology are included in that period, or at least four years if a satisfactory examination in these subjects has been passed previously to registration. Of being twenty-one years of age, and of good moral character. Of apprenticeship or pupilage to a qualified apothecary, or of having been engaged at Practical Pharmacy under the supervision of a duly registered medical practitioner, possessing the suitable means of instruction, for a period of twelve months subsequently to having passed the Examination in Arts. Of having duly attended the following courses—viz.: Materia Medica and Pharmacy, during three months; Botany and Zoology, during three months; Chemistry, during six months; Practical Chemistry (in a laboratory), during three months; Anatomy and Physiology, during six months; Practical Anatomy, with Dissections, during twelve months; Medicine (the Principles and Practice), during six months; Surgery (the Principles and Practice), during six months; Pathology, during three months; Midwifery and Diseases peculiar to Women and Children, during six months; Practical Midwifery; attendance on at least twenty cases in a recognised Lying-in Hospital; instruction in Vaccination from a duly registered medical practitioner; Forensic Medicine, during three months; Mental Disease, during three months; Hygiene, one course; attendance on the practice of a recognised medico-chirurgical hospital or hospitals, with the clinical instruction, during at least four winter and three summer sessions; practical instruction, with care of patients, as apprentice, pupil, clinical clerk, or assistant in hospital or dispensary.

The examinations for "the Licence to practise the Profession of Apothecary" is divided into three parts:—The first part comprehends Materia Medica and Pharmacy, Elementary Chemistry, Botany, Zoology, and Human Osteology; the second part Anatomy, Physiology, Histology, and Practical Analytical Chemistry; and the third part Medicine, Surgery, Midwifery, Mental Disease, Forensic Medicine, and Hygiene. The examinations commence on the first Monday in the months of January, April, July, and October, and are conducted by printed papers and orally.

Candidates are eligible for the first part of the Professional Examination at the termination of the second year of study; and candidates for the second part, after having passed the first successfully, at the end of the third year of study; and candidates for the final, after having passed the previous examinations successfully, at the completion of the prescribed courses of professional study. The fee for every examination and re-examination is £2 2*s.*, half to be returned in case of failure. Ten shillings is the charge for the licence of the Hall.

THE ARMY, NAVY, AND INDIAN MEDICAL SERVICES.

Admission into the Army and Indian Medical Services is gained as the result of competitive examination. Candidates for both services must, before being admitted to examination, possess the double qualification to practise Medicine and Surgery, and be registered under the Medical Act, and must also furnish satisfactory certificates of moral character. Candidates for the Army must be between the ages of twenty-one and twenty-eight, in good health, and both parents of unmixed European blood; for the Indian Service, between twenty-two and twenty-eight, of sound bodily health, and natural born subjects of Her Majesty. Both are examined as to physical fitness by a Board of Medical Officers. These conditions being satisfied, the candidate is admitted to the competitive examination, which is usually held in London twice a year, in the months of February and August. The subjects of examination are divided into *compulsory* and *voluntary*. The former comprise Anatomy and Physiology, Surgery, Medicine, including Therapeutics and the Diseases of Women and Children, Chemistry and Pharmacy, and a practical knowledge of Drugs. The eligibility of the candidate for admission into the service is determined by the result of this part of the examination. The *voluntary* subjects are French, German, Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany, with especial reference to Materia Medica, and for the Indian service Hindustani. Although the results of the examination on voluntary subjects do not affect the question of the eligibility of the candidate for a commission, they influence his position on the lists, which is determined by the numbers obtained under the two heads conjointly. After having passed this examination, the successful candidates for both services are sent to the Army Medical School at Netley as "surgeons on probation," with the rank of lieutenant and the daily pay of 8*s.*, to go through a four months' course of special instruction in the duties required of them in the service. The staff of the school consists of four professors, all of them men of acknowledged ability and high standing in their special departments. Surgeon-General Sir J. Longmore, Kt., C.B., is Professor of Military Surgery; Deputy-Surgeon-General D. B. Smith, M.D., of Military Medicine; Surgeon-Major de Chaumont, M.D., F.R.S., of Military Hygiene; and Dr. Aitken, F.R.S., of Pathology. To each of these an Army Medical Officer is attached as Assistant Professor. The lectures on Military Surgery include gunshot and other wounds, transport of sick and wounded, duties of army medical officers in the field, during sieges, and on board troopships and transports, &c. Those on Military Medicine treat of tropical and other diseases to which soldiers are exposed in the course of their service, the mortality and invaliding by disease, in peace and war, at home and abroad. The course of Hygiene comprises the examination of water and air, the general principles of diet, with the quality and adulterations of food and beverages, the sanitary requirements of barracks, hospitals, and camps, the clothing, duties, and exercises of the soldier, and the circumstances affecting his health with the best means of preventing disease, and instruction in the mode of preparing the various statistical and other returns required of the medical officer. The surgeons on probation are detailed for duty in the wards of the hospital, under the Professors and Assistant-Professors of Medicine and Surgery, and receive

Digitized by Google

practical instruction in the mode of examining recruits. The Surgeons on probation are provided with quarters, and are members of the excellent mess established at Netley. After having passed through the course of instruction they are examined on the subjects taught in the school, and their position on the list recommended for commissions, is determined by the combined results of the competitive and final examinations. At the close of each session five prizes are awarded: the Herbert prize of £20 to the surgeon on probation who has obtained the highest number of marks at the London and Netley examinations conjointly; the Parkes Memorial Bronze Medal to the one who gains the highest number of marks in the examination on Hygiene at Netley, combined with those given for the answers to a special question set on the same subject; the Martin Memorial Gold Medal to the highest number of marks in the final examination on Military Medicine, with the addition of those gained for a special question connected with it; the Montefiore Gold Medal and £20, awarded in the same manner for Military Surgery; and the Montefiore Second Prize, consisting of works on Military Surgery, to the surgeon on probation who obtains the second highest numbers in this branch.

Surgeons are promoted to be Surgeons-Major on completing twelve years' full-pay service, of which three must have been abroad. Before being promoted they will be required to pass an examination intended to test their progress and proficiency in all those branches of knowledge which are essential to their continued efficiency as medical officers, which may be taken at any time between the fifth and tenth year of service. It will embrace the following subjects:—*a.* Surgery, operative and practical, including field surgery and transport of sick and wounded. *b.* Medicine and pathology, including practical pharmacy and modes of prescribing and administering remedial measures, food, drink, &c. *c.* Hygiene, within the limits treated of in "Parkes' Practical Hygiene." *d.* Duties of executive medical officers during peace and war at home and abroad, and at sea, as defined in the various codes of regulations issued for their guidance. Medical officers possessing the following qualifications will be exempted from examination in medicine, surgery, and hygiene respectively: *a.* The Fellowship of any Royal College of Physicians or Surgeons of Great Britain or Ireland, granted under a higher standard of qualification than that for Licentiate or Member, will be accepted in lieu of an examination in medicine and surgery. *b.* The diploma in Hygiene and State Medicine, or any corresponding diploma of any University in Great Britain or Ireland, such diploma being granted after examination, will be accepted in lieu of an examination in this subject. A certificate will be required from a recognised teacher of surgery in any medical school at home or abroad in which operative surgery is taught, showing that the medical officer has gone satisfactorily through a complete course of operative surgery during the period within which the examination must be taken, and that he is a competent operator. A report on any subject of a practical professional character to be selected by the officer himself, and certified to be his own composition, and in his own handwriting, will also be required.

The selection of Surgeons-Major for advancement to the grade of Brigade Surgeon is made on the grounds of ability and merit, in determining which the following points will be considered:—The officer to be so selected must have been favourably reported on by the several military and departmental officers under whom he may have served, as set forth in their Annual Confidential Reports. He must be physically fit for general service, and have the necessary qualifying foreign and Indian service under existing rules. He must, before he can be selected for promotion to the grade of Brigade Surgeon, establish before an examining board, appointed for the purpose by the Director-General, his efficiency in the following subjects:—*a.* Hospital organisation and administration in peace and war. *b.* The administration, interior economy, command, and discipline of the Medical Staff Corps and bearer columns. *c.* The relations of the medical to all other departments and corps of the army, as defined by the various Codes of Regulations in force. *d.* Recruiting and invaliding. *e.* The management of sick and wounded in war. *f.* Field Medical organisation. *g.* The transport of the sick and wounded by land and sea. *h.* The medical and surgical equipment and hospital arrangements for an army corps. *i.* The duties and responsibilities of medical officers, quartermasters, and non-commissioned officers and men of the Medical Staff Corps in regard to the charge and supervision of stores and equipments, and the nursing, dieting, and general management of the sick. *k.* The sanitary duties of medical officers in charge of camps and hospitals in the field and at the base of operations. *l.* The sanitary inspection and equipment of hospital ships and troop transports, and all other sanitary duties in camps, garrisons, and quarters. *m.* The origin, progress, and best methods of dealing with outbreaks of epidemic disease among troops under any given circumstance. *n.* The most approved methods of securing the sick, and especially the wounded, against pyæmia, septicæmia, and all other forms of blood-poisoning, and the management and treatment of such outbreaks when they occur. *o.* Questions on operative surgery and practical medicine will also form part of this examination. A medico-topographical report will be required of any district or country in which British troops have been, or are likely to be, actively employed, as well as a sketch of the medical arrangements suitable for an army corps operating in such a district or country, compiled by the officer, and certified to be his own composition and in his own handwriting.

Brigade Surgeons, to be eligible for selection as Deputy Surgeons-General, must have served abroad at least ten years, of which three must have been in India. All officers under the rank of Deputy Surgeon-General are placed on the retired list at the age of fifty-five, and those of that rank and Surgeons-General at the age of sixty.

INDIAN MEDICAL SERVICE.

From date of leaving Netley till embarkation, 10*s.* per diem. Pay and allowances in India.

,, in Bengal	2700 0 0		

The regulations above noted respecting the promotion of Surgeons and Surgeons-Major are equally applicable to the Indian Medical Service.

ROYAL NAVY.

The conditions of admission into the Naval Medical Service are the same as those for the Army; but the candidate is also required to declare his readiness to engage for general service, and to proceed on duty abroad whenever required to do so. After having passed the competitive examination in London the successful candidate will receive a commission as surgeon in the Royal Navy, "and will undergo a course of practical instruction in Naval Hygiene at Haslar Hospital." At present Fleet Surgeon Walter Reid, M.D., has been appointed to Haslar "for instruction of surgeons on entry," and Surgeon Gilbert Kirker, M.D., "to assist in instruction of surgeons on entry"; but we have no information as to the length of the course, the conditions under which it is conducted, or the subjects professed to be taught.

Surgeons are promoted to Staff Surgeons after twelve years from date of entry, provided they pass the requisite examination, and Staff Surgeons to Fleet Surgeons after twenty years' service, if recommended by the Director-General. Deputy-Inspectors-General are promoted by selection from the Fleet Surgeons, and Inspectors-General from the Deputy Inspectors-General having three years' foreign, four years' mixed, of which not less than two have been abroad, or five years' home service in such appointments as preclude foreign service, provided they have not refused to go abroad when called upon to do so. Inspectors and Deputy Inspectors-General are retired compulsorily at sixty, and other grades at fifty-five years of age, and all ranks at any time if they have not served for five years. In calculating service for retired pay time on half-pay will be taken as equivalent to one-third service on full-pay.

METROPOLITAN HOSPITALS AND MEDICAL SCHOOLS.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—The clinical practice of the hospital comprises a service of 750 beds, of which 676 are in the hospital at Smithfield, and 75 are for convalescent patients at Swanley.

Four house-physicians, ten house-surgeons, and a midwifery assistant are appointed annually, each of them holding office for one year, and provided with rooms by the hospital authorities. The ophthalmic house-surgeon is appointed for six months, and is eligible for re-election for a second term of six months. The senior assistant chloroformist and junior assistant chloroformist are appointed annually, and are provided with rooms. Two qualified assistant electricians are appointed every three months. No fee is paid for any of these appointments, and each receives a salary of £25. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical out-patients, and the dressers in the special departments are chosen from the diligent students. Forty ward-dresserships are given annually to the students who pass the best examination in the subjects of study of the first year. Other ward dresserships may be obtained by payment of the usual fees.

A college is attached to the hospital, in which students can reside, subject to the college regulations.

Foundation and other Prizes.—Open Scholarships in Science of the value of £130 each, tenable for one year, will be competed for in September. Candidates must not be more than twenty-five years of age for one, and twenty-one for the other, and must not have entered to the medical or surgical practice of any metropolitan medical school. The subjects of examination are Physics, Chemistry, Botany, Physiology (not more than four subjects to be taken), and Zoology.—Preliminary Scientific Exhibition (founded 1873). The subjects of examination are identical with those of the Open Scholarship in Science. This Exhibition, of the value of £50, is tenable for one year. The Examination is confined to students of the hospital of less than six months' standing, and will be held in October. The Jeaffreson Exhibition, of the value of £50, and tenable for two years, is awarded after examination in the subjects of General Education. It is now an Open Exhibition. A Senior Scholarship, £50, in Anatomy, Physiology, and Chemistry. Kirke's Scholarship, and Gold Medal in Clinical Medicine, value forty guineas. Lawrence Scholarship, and Gold Medal, of the value of forty guineas (founded in 1873 by the family of the late Sir William Lawrence). Two Brackenbury Scholarships in Medicine and Surgery, £30 each. Junior Scholarships in the subjects of study of the first year: 1st, £50; 2nd, £30; 3rd, £20.

During the last year a prize for Anatomy has been founded by the late Mr. Henry Skinner, in memory of his brother, and by Miss Shuter, in memory of her brother, formerly assistant surgeon to St. Bartholomew's Hospital.

CHARING-CROSS HOSPITAL AND COLLEGE.—Total fees, £94 10*s*., if paid in a single sum on entry, or £105 if paid in five instalments. General students pay proportionately lower fees, and are admitted without additional fee to the courses of Clinical Medicine and Surgery, to the new classes of systematic practical instruction in Medicine and Surgery, and to the practice of the Royal Westminster Ophthalmic Hospital. They alone are entitled to compete for the Scholarships, Gold Medal, and Pereira Prize.

Preliminary Science Instruction.—Arrangements have been made for students desirous of undergoing a course of instruction in science, such as that required for the Preliminary Scientific (M.B.) Examination of the University of London, to attend at the Normal School of Science, South Kensington.

Two Entrance Scholarships, of the value of £30 and £20 respectively, tenable for one year, are awarded annually in October, after a competitive examination in the following subjects:—*Compulsory*—English, Latin, Mechanics, and Mathematics; *Optional* (only one of which may be selected)—Chemistry, German or French, the subjects being those of the matriculation examination of the University of London. Candidates must give notice of their intention to compete on or before Monday, September 20th, 1886. Two scholarships are open for competition among general students: the Llewellyn Scholarship of £25, for students who have just completed their attendance on lectures; and the Golding Scholarship of £15 for students who have just completed their first year. The Pereira prize of £5 is open to all general students, and is awarded annually for the best clinical reports. The Governors' Gold Medal is given for excellence in clinical work. Silver or Bronze Medals are awarded to the most distinguished students in all classes; and special prizes in the classes of Dental Surgery, Practical Surgery, and Practical Histology.

ST. GEORGE'S HOSPITAL.—Perpetual pupils, by payment of £130 in three instalments, or £125 in one sum, are entitled to admission to the medical and surgical practice; to compete for prizes and exhibitions; to hold the appointment of house-physician and house-surgeon, assistant house-physician, assistant house-surgeon, ophthalmic assistant, registrar's assistant, and to become clinical clerks for two periods of three months each, and dressers for similar periods. Gentlemen are admitted to the hospital practice and lectures required by the College of Physicians and Surgeons and the Society of the Apothecaries on payment of £45 at the commencement of the first year of study, £45 at the commencement of the second year of study, £20 for the third, and £15 for each subsequent year of attendance. These payments entitle the pupil to hold the offices of clinical clerk and dresser for three months each, and to become a candidate for the offices of medical and surgical registrar and demonstrator of anatomy and curator of the museum. These are all salaried offices. The obstetric assistant is resident, with a salary of £100.

Entrance Scholarships.—£125, open to sons of medical men; two of £50 each, open to all students commencing their medical studies; £90, open to students who have passed the Cambridge First M.B.; £75, open to students who have passed the Oxford First M.B. or Cambridge Second M.B.

Prizes.—The William Brown Exhibition of £100 per annum, tenable for two years, open to any perpetual pupil of St. George's who is under twenty-five years of age, and who shall have obtained a diploma or licence entitling him to be registered as a practitioner of medicine or surgery in England, within two years previously to the period fixed for the examination (July). The examination is to test the proficiency of the candidate in Medicine, Midwifery, and Surgery, including Ophthalmic Surgery. The William Brown Exhibition of £40 per annum, tenable for three years, for general fitness for the exercise of the medical profession and for moral conduct, open to perpetual pupils in their fourth year of study. Sir Charles Clarke's Prize (interest of £200 consols) for good conduct; the Brackenbury Prize in Medicine, value nearly £40; the Brackenbury Prize in Surgery, value nearly £40; the Treasurer's Prize, £10 10*s*.; the Thompson Medal; the Bronze Prize for Clinical Surgery; the Acland Prize for Clinical Medicine; the Pollock Prize in Physiology; the Henry Charles Johnson Prize in Anatomy; and General Proficiency Prizes, value £10 10*s*. each, for students of each year.

GUY'S HOSPITAL.—House-physicians and house-surgeons, obstetric residents, dressers, clinical and other clerks, are selected from the students, according to merit, and without payment. The house-physicians, of whom there are three constantly on duty, one as junior and two as seniors, hold office for six months each, the first two months in the former capacity, the other four in the latter. The duty of the junior house-physician is to attend in the medical out-patient room three times a week, in a room adjoining that occupied by the assistant-physician for the day, and prescribe for those patients who are not seen by the assistant-physician. The senior house-physicians are chiefly occupied in the medical wards, and attend to all emergencies that may arise in the absence of the physicians. The house-surgeons, of whom there are also three on duty, hold offices for six months each. During the first two months the house-surgeon has the general superintendence of the Surgical Casualty Department; during the remainder of his time he lives in the hospital, being boarded free of expense. For two months, as second house-surgeon, he has charge of cases in special wards, and assists in the Out-patient Department; and subsequently, as senior house-surgeon, he has, in the absence of the surgeons and assistant-surgeons, the care of the patients in the surgical wards The dressers

Digitized by Google

are selected from those gentlemen who have completed their third winter session, and who have been most diligent in the junior appointments. They hold office for six months each. Three are attached to each surgeon. During their week of special duty they reside in the hospital, and board with the house-surgeons. Two obstetric residents reside and are boarded in the hospital.

Scholarships, Prizes, &c. Open scholarships of the value of £131 5*s.* in Arts, Latin, Greek, Mathematics, and modern languages. Open Scholarship of £131 5*s.* in Science. Subjects: Inorganic Chemistry, Zoology, Botany, Physics (these will be competed for on Monday, September 27th), At the end of the summer session: first prize, £50; second prize, £25. Subjects: Anatomy, Physiology, Chemistry, Materia Medica and Botany, or Comparative Anatomy.—For students in their second year: First prize, £25; second prize, £10. Subjects: Anatomy, Physiology. The Sands Cox Scholarship of £15 per annum for three years. Subject: Physiology. The Michael Harris prize of £10 for Anatomy. For students in their third year: First prize, £25; second prize, £10. Subjects: Medical and Surgical Anatomy, Midwifery, and Therapeutics. Fourth year's students: First prize, £25; second prize, £10. Subjects: Medicine, Surgery, Midwifery, and Medical Jurisprudence. For senior students: The Treasurer's Gold Medal in Medicine; the Treasurer's Gold Medal in Surgery; The Gurney Hoare Prize of £25 for Clinical Medicine and Surgery; the Beaney Scholarship of 30 guineas for Pathology; the Mackenzie Bacon Prize of 10 guineas for Ophthalmoscopy; the Mackenzie Bacon Prize of £15 for Nervous Diseases. The Physical Society awards the following prizes: Two of £5 each to the members who send in the best essays on selected subjects; prizes of £10 and £5 for the best papers read before the Society; and one of £5 to the member who has most distinguished himself in the debates of the session.

KING'S COLLEGE.—The physicians' assistants, the physician-accoucheur's assistant, the ophthalmic clinical assistant, the clinical clerks, and the house-surgeons and dressers, are selected by examination from among those matriculated students of the college who are pupils of the hospital. Rooms are provided within the walls of the college for the residence of a limited number of matriculated students. Rooms and commons are provided at the hospital for the resident officers free of charge.

Scholarships.—Warneford Scholarships: Two of £25 per annum for three years for Literature. Science: One of £50 and one of £25 each for two years. Sambrooke: One of £60 and one of £40 for Science. Rabbeth Scholarship of £20 per year for Science. College Scholarships: One of £40 per annum for two years; one of £30 for one year; three of £20 for one year. The Daniell Scholarship, for Chemistry, of the annual value of £20. Sambrooke Registrarships, of the annual value of £50 each, and tenable for two years, are open to all matriculated students who have filled any one of the higher appointments of the hospital, or who have become Associates. The Leathes Prizes, value £7, and the Warneford Prizes, value £40, are given annually amongst the matriculated medical students. Two Medical Clinical Prizes, one of £3 for the winter session, and one of £2 for the summer session, and two Surgical Clinical Prizes, of £3 each, are given. The Todd Medical Clinical Prize consists of a bronze medal and books to the value of £4 4*s.* The Tanner Prize for Obstetric Medicine, value £10, and the Carter Gold Medal and Prize for Botany, value £15, are given annually in July. Class Prizes, value £3 3*s.* each, are awarded annually in every subject. A Warneford Scholarship of £25 per annum for two years for third-year subjects is awarded annually to resident students only.

LONDON HOSPITAL AND COLLEGE.—The Medical School of the London Hospital is under the direction of a college board, composed of six members of the hospital staff and six of the house committee. The executive authority is committed to a warden. The hospital, which is the largest in Great Britain, contains nearly 800 beds. Last year the number of in-patients was 8732, out-patients 67,942.

The following Scholarships and Prizes will be offered for competition during the ensuing winter and summer sessions:—Two Entrance Scholarships in Natural Science, of the value of £60 and £40 respectively, will be offered for competition on September 20th, 21st, and 22nd, 1886. The subjects are Physics, Botany, Zoology, and Inorganic Chemistry. The successful candidates must forthwith become full pupils of the hospital and school, if not already entered; and are not eligible to compete for the Buxton Scholarships: -The two Buxton Scholarships, value £30 and £20, will be offered for competition on September 27th, 28th, and 29th, 1886. The subjects are those appointed by the General Council of Medical Education and Registration as the subjects of the Preliminary Examination. A Scholarship, value £25, in Anatomy, Physiology, and Chemistry, will be competed for at the end of the winter session by first and second year students. A Scholarship, value £20, in Anatomy and Physiology for first-year students. (At the commencement of the summer session.) The Letheby Prize, value £30, for Proficiency in Chemistry. (At the end of the summer session.) Open to all full students who have completed their second summer session up to the termination of their fourth year from entrance. A Hospital Scholarship, value £20, for proficiency and zeal in Clinical Medicine. (At the end of the winter session.) A Hospital Scholarship, value £20 for proficiency and zeal in Clinical Surgery. (At the end of the winter session.) A Hospital Scholarship, value £20, for proficiency and zeal in Clinical Obstetrics. (At the end of June.) The Duckworth Nelson Prize, value £10, will be offered biennially for competition at the end of the winter session, and be open to all students on similar conditions to those of the Hospital Scholarships. The subjects of examination will be Practical Medicine and Surgery. The Hutchinson Prize, value £35, will be given triennially to the author of the best essay upon a subject in Clinical Surgery. Candidates must be full students of the hospital who have not been registered more than ten years. Out-patients' Dressers' Prizes. Six prizes, of the aggregate value of £60, will be offered for competition at the end of the winter session. Candidates must pass an examination in Minor Surgery, have dressed diligently for twelve months, and have passed the Primary Examination of the Royal College of Surgeons. Two Dissection Prizes, value £6 and £4. Special classes are held throughout the year for the Preliminary Scientific Intermediate M.B. Examinations of the University of London and for the Primary and Pass Examinations for the Fellowship of the Royal College of Surgeons. Special entries can also be made for Medical and Surgical Practice, the Operative Surgery classes, &c. The very extensive alterations that have been made to the school premises during the past year will afford complete provision for the teaching of all branches of medical science, the accommodation now afforded being more than double that which was provided in the old buildings.

ST. MARY'S HOSPITAL.—There are five resident medical officers, four of whom are appointed for twelve months, and one, the obstetric officer, for six months, who board free of expense in the hospital. These appointments are awarded after competition, without additional fee. Two Demonstrators of Anatomy are appointed annually, with a salary of £70 and £50 respectively; a Demonstrator of Physiology, at £100 a year; and a Demonstrator of Histology, at £50 a year. All these officers are eligible for re-election. There is also a Demonstratorship in Pathological Anatomy, of the value of £15, and tenable for six months; the holder of this scholarship will assist the pathologist in the discharge of his duties in the museum and dead-house. Two Prosectors of Anatomy and two Assistant Demonstrators of Physiology are appointed annually, and receive a certificate and £5 each for satisfactory service in their respective departments. All students are required to perform the duties of clinical clerk and dresser during the last two years of their curriculum. Students of the third year and of subsequent years are also appointed as clerks and dressers to assist the physicians and surgeons in charge of the out-patients. In addition to the instruction given in the wards daily, distinct Clinical Lectures are given on Fridays throughout the academical year at 3.30 P.M. The hospital contains 270 beds, 130 of which are devoted to medical and 140 to surgical cases. Two wards are appropriated to the Diseases of Children, and one to those of Women; beds are also provided for Ophthalmic, Aural, and Cutaneous cases.

Scholarships, Prizes, and Appointments: Scholarships offered for open competition previously to entering at the Medical School.—Entrance Scholarships: The following will be offered for competition on Sept. 30th and Oct. 1st:—One Scholarship in Natural Science, of the value of 100 guineas, open to any gentleman who has not completed a

Digitized by Google

winter session of study at a medical school. Three Scholarships in Natural Science, each of the value of 50 guineas, under the same conditions. One Scholarship of the value of 100 guineas, open to students from Epsom College, being sons of medical men, and who have not completed a winter session of study at a medical school. Two Scholarships, each of 50 guineas, open to students from the Universities of Oxford, Cambridge, or other University, who have not entered at any London medical school.

In addition to the Open Entrance Scholarships, Class Prizes, and usual Appointments, Scholarships will be offered for competition at the end of each year, open to all pupils. These Scholarships are of the value of £20, £25, and £30, for the first, second, and third years respectively.

A residence for students, 33, Westbourne-terrace, W, in connexion with the hospital, is under the charge of a warden (Dr. Robert Maguire), and the dean is prepared to receive applications from students desiring to enter upon residence during the ensuing session. Terms: 90 guineas for the academical year, payable 30 guineas in advance, on Oct. 1st, Jan. 1st, and May 1st, to include special instruction by the demonstrators on four days a week.

MIDDLESEX HOSPITAL.—There is a special Cancer Department, affording accommodation for thirty-three in-patients, whose period of residence in the hospital is unlimited. Classes, open to all the students, are held for practical instruction in medicine, midwifery, in the microscopical examination of healthy and diseased tissues, and also in the application of bandages and other surgical apparatus. Students are allowed to take out to read at their own homes the books from the large and carefully selected medical library of the school. The museum has recently been rearranged, and a complete catalogue prepared of the various specimens. Two Entrance Scholarships, of the annual value of £50 and £30, and tenable for two years, are offered for competition at the commencement of the winter session. An Exhibition in Elementary Anatomy, Osteology, and Physiology, value £10 10s., is awarded to students at the end of their first year. The Lyell Medal is awarded annually for proficiency in Surgical Anatomy and Practical Surgery. The Hetley Prize is awarded annually for Clinical proficiency. Two Broderip Scholarships, of the annual value of £30 and £20, tenable for two years, are awarded to those students who pass the best examination at the bedside and the post-mortem room. The Murray Medal and Scholarship, founded in connexion with the University of Aberdeen, is awarded every third year to a student of this hospital; it will be next awarded in May, 1889. The Governors' Prize of 20 guineas is also awarded annually to the student after his third winter session who shall pass the best clinical examination in the out-patient departments. Valuable class prizes are also given, and fourteen resident clinical appointments are annually awarded, after competitive examination, to students who have completed their education and complied with the regulations of the school.

Arrangements have been made for students desirous of undergoing a course of instruction in Science, such as that required for the Preliminary Scientific (M.B.) Examination of the University of London, to attend such a course at the Normal School of Science, South Kensington. Fee for the whole course, £35. Students who enter for this course will be allowed a deduction of £20 on the fees for the medical curriculum.

ST. THOMAS'S HOSPITAL.—*Prizes and Appointments for the year 1886-87.*—For First-year's students: Two Entrance Scholarships in Natural Science of the value of £100 and £60 respectively, open to all first-year's students, will be awarded during the first week in October, after an examination in Physics, Chemistry, and either Botany or Zoology at the option of the candidate; the William Tite Scholarship, the proceeds of £1000 Consols (£30 per annum), is awarded each year; also prizes of £20 and £10; summer £15 and £10. For second-year's students: The Peacock Scholarship of 40 guineas, and the Musgrove Scholarship of 40 guineas, are awarded biennially to the students who shall take the highest place in the first-class list in the examinations at the end of the second winter session; they are tenable for two years, provided the holder obtains a place in the first class in the subsequent examinations; making the winter prizes £42, £20 and £10; summer, £15 and £10; with the dresserships and the clinical clerkships. For third-year's students (winter): Second Tenure of Scholarship £42, and prizes of £20, £15, and £10; summer, £15 and £10. Clinical clerks and dressers are selected according to merit. The Grainger Testimonial Prize of £15 is awarded annually to students, who shall be from three to six years' standing, for the best Anatomical or Physiological Essay, to be illustrated by preparations and dissections. The Cheselden Medal for Surgery and Surgical Anatomy, and the Mead Medal for Practical Medicine, are awarded annually to fourth-year's students. The Solly Medal, with a prize from 10 to 20 guineas, will be awarded biennially to a student of the third, fourth, fifth, or sixth year, for the best report of Surgical cases. The next award will be made in 1888. The Treasurer's Gold Medal, for general proficiency and good conduct, is awarded annually to a fourth-year's student.

Classes in Practical and Operative Surgery are held four times a week for six weeks prior to the final examinations of the Examining Board in January, April, and July. In connexion with these classes, Clinical Instruction is given in the wards by the resident assistant-surgeon, and a course of demonstrations on Museum Specimens is given by the curator, Mr. Shattock.

UNIVERSITY COLLEGE, LONDON.—*Composition Fees.*—1. For the entire medical education required by the Examining Board in England and the Society of Apothecaries, 125 guineas, if paid in one sum at the commencement of the course; 130 guineas, if paid by instalments, as follows—first year, 60 guineas; second year, 50 guineas; third year, 20 guineas. 2. For the classes required by the Examining Board to be attended at a medical school, 100 guineas, if paid in one sum; 105 guineas, if paid by instalments, as follows—first year, 50 guineas; second year, 35 guineas; third year, 20 guineas. 3. For the whole course of instruction for the Intermediate Examination in Medicine of the University of London, 50 guineas. 4. For the course of instruction for the Final M.B. Examination of the University of London, 70 guineas, if paid in one sum; 72 guineas, if paid by instalments, as follows—first year, 40 guineas; second year, 32 guineas. 5. Composition fee for Dental Students, 60 guineas.

Exhibitions, Prizes, &c.—Three Entrance Exhibitions, of the respective values of £100, £60, and £40 per annum, tenable for one year, are annually awarded, upon examination by printed papers, to gentlemen who are about to commence their first winter attendance in a medical school. The subjects of the examinations are—Chemistry, Physics, Botany, and Zoology. The next examination will take place at the College on September 29th and 30th. The Atkinson Morley Surgical Scholarship of £45, tenable for three years, is annually awarded to the student who, upon examination, is found to possess the greatest proficiency in the Theory and Practice of Surgery. The Sharpey Physiological Scholarship of about £105 per annum, tenable for three years, for proficiency in Biological Science. Filliter Exhibition: a prize of £30 is awarded annually, in July, to the most proficient student in the class of Pathological Anatomy. An Atchison Scholarship, value about £55 per annum, tenable for two years. The Erichsen Prize, a surgeon's operating case of the value of £10 10s., awarded yearly to the student of the class of Practical Surgery who shall most distinguish himself by manipulative skill. The Morris Bursary of £25 a year, tenable for two years. Besides the above, gold and silver medals, and other prizes, are awarded in each class.

WESTMINSTER HOSPITAL.—The hospital contains upwards of 200 beds. There are separate departments for Diseases of the Eye, Ear, Skin, Teeth, and Throat, and for Diseases of Women. The Anatomical Museum is constantly open to the students. There are also a Pathological Museum and a Materia Medica Museum.

A curator of the museum and pathologist, with a salary of 50 guineas, and a medical and surgical registrar, are appointed annually, each with a salary of £40. Two house-physicians, two house-surgeons, and a resident obstetric assistant are appointed for six months after examination, and are provided with rooms and commons. The Senior house-physician, who is also the chloroformist to the hospital, and the senior house-surgeon who performs special duties, receive in addition an honorarium of 20 guineas each. Clinical assistants to the physicians and surgeons, and to the officers in charge of special departments, are appointed from students of the fourth year.

Digitized by Google

Scholarships and Prizes.—The Guthrie and Entrance Scholarship, on alternate years, each £40 a year, and one Entrance Scholarship value £40. Entrance Scholarship, summer session, value £40. The Treasurers' Prize, an exhibition in Anatomy, Physiology, and Chemistry, value £10 10*s.*, tenable for one year for first-year's men. The President's Prize, a Scholarship in Anatomy, Histology, and Physiology, value £21, given by his Grace the Duke of Westminster, President of the Hospital, to a student of the second year (to be styled Assistant Demonstrator). At the end of the fourth winter session, prizes of £5 each (books or instruments) in Clinical Medicine and Clinical Surgery. Frederick Bird Medal and Prize, value £15. Subjects of examination: Medicine, Midwifery, Diseases of Women and Children, and Pathology. Chadwick Prize for General Proficiency, £21 (books or instruments), to the most meritorious student or students of any year not exceeding the fifth. In most of the classes special prizes, value about 2 guineas each, are given by the lecturers.

GREAT NORTHERN CENTRAL HOSPITAL, Caledonian-road, Consulting Surgeon: Frederick Le Gros Clark. Physicians. Drs. Cholmeley, Cook, Burnet, Beale, and Beevor. Obstetric Physicians: Drs. Gustavus C. P. Murray and Fancourt Barnes. Surgeons: Messrs. W. Adams, W. Spencer Watson, J. Macready, C. B. Lockwood, and G. H. Makins. Ophthalmic Surgeon: Mr. Jonathan Hutchinson, jun. Aural Surgeon: Mr. A. E. Cumberbatch. Choloformist: Mr. George Eastes. Dental Surgeon: Mr. E. Keen. House-Surgeon: Mr. A. Frank Whitwell. House-Physician: Mr. Donald Gunn. Dispenser: Mr. J. F. Dunstan.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Consulting Physicians: Dr. C. J. B. Williams, F.R.S., Dr. W. H. Walshe, Dr. R. Quain, F.R.S., Dr. J. E. Pollock. Consulting Surgeon: Professor John Marshall, F.R.S. Physicians: Drs. E. S. Thompson, C. T. Williams, R. D. Powell, J. Tatham, R. E. Thompson, and F. Roberts. Surgeon: Mr. R. J. Godlee, F.R.C.S. Assistant-Physicians: Drs. T. H. Green, J. M. Bruce, J. Fowler, P. Kidd, C. Y. Biss, and C. T. Acland. Pathologist: Dr. P. Kidd. Dental Surgeon: Mr. C. J. Noble. Resident Medical Officer: Dr. H. D. Waugh. Secretary: Mr. H. Dobbin. Four Clinical Assistants reside in the hospital for a period of six months. Pupils are admitted to the practice of the hospital: terms £3 3*s.* for three months; six months, £5 5*s.*; perpetual, £10 10*s.* Lectures and Clinical Demonstrations are given throughout the year by members of the medical staff. The medical practice of the hospital is recognised by the University of London, the Apothecaries' Company, and the Army and Navy and Indian Medical Boards. The hospital contains 321 beds in the two buildings.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road.—Established 1814. Consulting Physician: Dr. Horace Dobell. Physicians: Drs. Hensley, Gilbart-Smith, Finlay, White, Pringle, and Oswald Browne. Assistant-Physicians: Drs. Arthur Davies, Herbert Habershon, and Edward Stewart. Consulting Surgeon: Mr. Jonathan Hutchinson. Surgeon: Mr. A. Pearce Gould. House-Physicians: Messrs. Harrold Simmons and Frank T. Wethered. In-patients (1885), 122; out-patients (1885) 23,030. This hospital has recently been enlarged by the addition of a very complete out-patients' department, and also by the erection of a new wing, which will provide accommodation for 80 in-patients.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury.—The new hospital, with the Finchley Branch, contains 180 beds and cots. The physicians attend every Monday, Tuesday, Wednesday, and Friday, at 2.30 P.M. In- and out-patients' practice and electrical room treatment at that hour. Physicians: Drs. Ramskill, Radcliffe, Hughlings Jackson, and Buzzard. Physcians for out-patients: Drs. H. Charlton Bastian, W. R. Gowers, and Ferrier. Assistant-Physicians: Drs. Ormerod and Beevor. Surgeons: W. Adams and Victor Horsley. Ophthalmic Surgeons: R. Brudenell Carter and Marcus Gunn. Aural Surgeon: A. E. Cumberbatch. House-Physicians: T. Wilson and F. Stedman. Medical practitioners and senior students may attend the practice after signing their names in the clerk's office.

ROYAL LONDON OPHTHALMIC HOSPITAL, Moorfields.—The hospital, founded in 1804, and considerably enlarged in 1876, now contains 100 beds for patients, which were occupied during last year by over 2000 persons. The out-patients are yearly over 20,000; attendances, 130,000. Operations are performed daily from half-past ten to one o'clock, and three surgeons attend on each day. Students are admitted to the practice. Fees for six months, £3 3*s.*; perpetual, £5 5*s.* Demonstrations and lectures are given during the winter. Students of the hospital are eligible for the office of house-surgeon, or may be appointed clinical assistants. The Secretary, Mr. Robert Newstead, will furnish further information, as may be desired.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand.—The hospital contains 50 beds; and the patients, who number 10,000 annually, are seen and operations performed daily at 2 o'clock. The following are the days of attendance of the surgeons: Mr. Power and Mr. Frost, Monday and Friday; Mr. Rouse and Mr. Hartridge, Tuesday and Saturday; Mr. Macnamara, Monday and Thursday; Mr. Cowell and Mr. Juler, Wednesday and Saturday. The practice of the hospital is open to students. Fees for six months, £3 3*s.*; perpetual, £5 5*s.* Students of the hospital are eligible for the post of house-surgeon. Special demonstrations and lectures will be given during the session. Secretary, Mr. T. Beattie-Campbell.

ROYAL ORTHOPÆDIC HOSPITAL, 297, Oxford-street.—Surgeons: Messrs. B. E. Brodhurst, H. A. Reeves, Charles Read, and William E. Balkwill. Assistant-Surgeon: Mr. H. F. Baker. House-Surgeon: Mr. W. B. Thomas. Secretary: Mr. Maskell. Operations on Mondays at 2 P.M. The hospital is open to all legally qualified practitioners. Pupils are admitted to witness the practice of the hospital on the following terms: six months, £3 3*s.*; twelve months, £5 5*s.*; perpetual, £10 10*s.*

DENTAL HOSPITAL OF LONDON MEDICAL SCHOOL, Leicester-square.—Lectures are delivered in winter on Mechanical Dentistry by Dr. J. Walker, on Wednesdays at 5 P.M. In summer, by Mr. Hutchinson, on Dental Surgery and Pathology, on Tuesdays and Fridays at 8 A.M., and by Mr. Arthur Underwood, on Dental Anatomy and Physiology (Human and Comparative), on Wednesdays and Saturdays, at 8 A.M. *Fees:* General fee for special lectures required by the curriculum, £15 15*s.*; fees for two years' hospital practice required by the curriculum, £15 15*s.*; total fees for lectures and practice, £31 10*s.* Hospital Surgeons: Messrs. Canton, Gregson, Hepburn, Storer Bennett, Underwood, and Woodhouse. Assistant-Surgeons: Messrs. Hern, Matheson, Parkinson, Read, Rogers, and Truman. Anæsthetists: Messrs. Braine, Bailey, Bird, and Mills. Assistant-Anæsthetists: Drs. Brunton and Hewitt. House-Surgeon: Mr. C. F. Rilot. Assistant House-Surgeons: Messrs. F. Colyer and R. W. Eouw. Medical Tutor: Mr. W. Paterson. The winter session will commence October 4th. All communications to be addressed to Mr. Morton Smale, Dean.

SEAMEN'S HOSPITAL (late *Dreadnought*), Greenwich, S.E. This institution is established for the relief of seamen of all nations. Casualties are received at all hours. Apartments are provided in the house of the Principal Medical Officer for students. Honorary Consulting Physicians: Dr. Robert Barnes, F.R.C.P., and Dr. Richard Quain, F.R.C.P. Visiting Physicians: Dr. John Curnow, F.R.C.P., and Dr. Herbert Tyrrell Griffiths, M.R.C.P. Honorary Consulting Surgeon: Vacant. Visiting Surgeon: Mr. G. Robertson Turner, F.R.C.S. Medical Officer, Well-street Dispensary: Mr. C. E. Cotes, F.R.C.S. Principal Medical Officer: Mr. W. Johnson Smith, F.R.C.S. House-Physician: Mr. E. H. Booth, M.B. House-Surgeon: Mr. C. Stuart Spong. Secretary: Mr. W. Thomas Evans.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, Queen-square, W.C., and Cromwell House, Highgate.—Physicians: Drs. W. B. Cheadle, Sturges, and Barlow. Assistant-Physicians: Drs. R. J. Lee, D. B. Lees, Montague Lubbuck, Abercrombie, and Angel Money. Surgeons: Mr. Howard Marsh, Mr. Edmund Owen, Mr. J. H. Morgan, Mr. Bernard Pitts, and Mr. Arbuthnot Lane. Ophthalmic Surgeon: Mr. R. Marcus Gunn. Surgeon-Dentist: Mr. A. Cartwright. Secretary: Mr. Adrian Hope. There are now 121 beds in the hospital, Great Ormond-street, and 52 beds at the country branch; total 173. In-patients last year, 1144; out-patients, 14,287. The practice at the hospital has recently been thrown open gratuitously to the pupils of the different hospitals and medical schools of London on conditions which may be ascertained of the Secretary.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, London, W.—This hospital has been recently enlarged, and is in full operation. It receives nearly 700

Digitized by Google

patients annually, besides having a large out-patient maternity. The pupils are permitted to see the practice in both departments. Medical pupils are received at all times of the year. Pupils enjoy unusual opportunities of seeing obstetric complications and operative midwifery, on account of the very large number of primiparous cases—upwards of three-fourths of the total admissions. Clinical instruction is given on the more important cases that present themselves in both departments. Certificates of attendance at this hospital are received by all universities, colleges, and licensing bodies; and a diploma is granted in Midwifery. Monthly nurses and midwives are received for training. For further particulars, applications should be made to the Secretary, at the hospital.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN, Waterloo-bridge-road. — Instituted 1816. Consulting Physicians: Dr. Wilks and Dr. John Williams. Physicians: Drs. W. A. Duncan, W. B. Haddon, W. Park, and W. R. Dakin. Surgeon: Mr. H. C. Jacobson. Assistant-Surgeon: Mr. E. Overman Day. Surgeon-Dentist: Mr. W. Whitehouse. Resident Medical Officer: E. H. Freeland. Secretary: Mr. R. G. Kestin. Advanced students in medicine, and such practitioners as may desire it, are permitted to attend the practice of this hospital gratis. If a certificate signifying such attendance be required, the sum of £5 5s. must be paid to the physicians and surgeons in ordinary conjointly.

HOSPITAL FOR WOMEN, Soho-square, W., Consulting Physician: Dr. Protheroe Smith. Physicians: Drs. Carter, Richard T. Smith, Holland, and Mansell-Moullin. Surgeon: Mr. H. A. Reeves. Assistant-Physicians: Drs. Bedford Fenwick and Oliver. Assistant-Surgeon: Mr. S. Osborne. Pathologist and Registrar: Dr. Norman Dalton. Anæsthetist: Dr. Dudley Buxton. In connexion with this institution there has for some years been a well-organised Clinical Department, which has lately been enlarged under the title of the London School of Gynæcology. To meet the want increasingly felt by medical men of an accurate knowledge of the ordinary diseases of women, ten gentlemen are appointed every three months to act as clinical assistants to the physicians and surgeons seeing out- and in-door patients. The appointments are nominally "open to qualified medical men and to students of medicine after their third year," but in the selection of candidates preference is naturally given to gentlemen already engaged in practice. The large numbers of out-patients afford quite unrivalled opportunities for practical instruction in the use of gynæcological instruments, and for the study of diseases peculiar to women. A course of lectures on the Anatomy and Physiology of the Female Pelvic Organs is given during each quarter by a member of the Staff. Clinical Lectures are given in the Operating Theatre on alternate Thursday afternoons at 3.30 P.M. throughout the winter and summer sessions. Valuable prizes are given, after examination, annually, open to past and present clinical assistants. Fee for the three months' course, £5 5s. Any further information can be obtained by letter, addressed to the Dean at the hospital.

VICTORIA HOSPITAL FOR CHILDREN, Chelsea, S.W., and Churchfields, Margate.—The hospital contains 60 beds and 12 at the home at Margate, and has a large out-patient department (over 500 weekly). Physicians: Dr. Julian Evans and Dr. Ridge Jones. Physicians to the out-patients: Drs. Albert Venn, T. Colcott Fox, F. D. Drewitt, and Henry Philpot. Surgeons: Messrs. Pick and Clutton. Surgeons to the Out-patients: Messrs. Churchill and Walter Pye. Dental Surgeon: Mr. Francis Fox. House-Surgeon: Philip D. Turner. Registrar: Paul F. Moline. Secretary: Captain W. C. Blount, R.N. Out-patients are seen daily as under:—Medical cases: Daily at 9 A.M.; also on Mondays and Thursdays at 1.30. Surgical cases: Daily, except Wednesday and Saturday, at 9.30 A.M. Dental cases: Saturdays at 9 A.M.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Consulting Physicians: Dr. Robert Barnes and Sir Andrew Clark, Bart., M.D. Consulting Surgeon: Mr. Buxton Shillitoe. Consulting Ophthalmic Surgeon: Mr. George Cowell. Physicians: Dr. Eustace Smith, Dr. Horatio B. Donkin, and Dr. H. Radcliffe Crocker. Surgeons: Mr. Arthur Cæsar, Mr. R. W. Parker, and Mr. L. A. Dunn. Assistant-Physicians: Dr. J. A. Coutts and Dr. Dawson Williams. Administrator of Anæsthetics: Mr. Thomas Bird. Medical Officer: Mr. J. Scott Battams. Secretary: Mr. Ashton Warner. Miss F. A. Davies, Lady Superintendent; Mrs. Fisher, Matron.

WEST LONDON HOSPITAL, Hammersmith-road, W.—This hospital has 100 beds. In 1885 there were 1269 in-patients and 14,933 out-patients under treatment. There are appointments for a House-Physician and two House-Surgeons, with board and residence, tenable for six months. Also appointments for a limited number of Clinical Assistants. Physicians: Drs. G. Goddard Rogers, D. W. C. Hood, and F. G. D. Drewitt. Physician for Diseases of Women: Dr. Albert Venn. Surgeons: Messrs. C. B. Keetley, F. Swinford Edwards, and W. Bruce Clarke. Surgeon for Diseases of the Eye: Mr. B. J. Vernon. Assistant-Physicians: Drs. W. P. Herringham, J. B. Ball, and Seymour Taylor. Assistant-Physician for Diseases of Women: Dr. J. A. Mansell Moullin. Assistant-Surgeons: Messrs. C. A. Ballance, H. F. Weiss, and B. Wainewright. Assistant-Surgeon for Diseases of the Eye: Mr. H. P. Dunn. Surgeon-Dentist: Mr. H. L. Albert. Pathologist: Mr. H. P. Dunn. Administrators of Anæsthetics: Messrs. T. Gunton Alderton and Rickard W. Lloyd. Secretary: Mr. R. J. Gilbert.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—Consulting Physician: Dr. W. S. Playfair. Consulting Surgeons: Sir Prescott G. Hewett, Bart., and Mr. W. Morrant Baker. Physicians: Drs. Fred. Taylor, James F. Goodhart, Nestor Tirard, and Fred Willcocks. Surgeons: Messrs. H. G. Howse, R. Clement Lucas, C. J. Symonds, and G. H. Makins. Ophthalmic Surgeon: Dr. W. A. Brailey. Dental Surgeon: Mr. R. Denison Pedley. House-Surgeon: Dr. Albert Martin. Hon. Secretary: Dr. I. Dobree Chepmell.

ALL SAINTS' CHILDREN'S HOSPITAL, 4, Margaret-street, and 59, Mortimer-street, W. Founded by the All Saints' Sisterhood in 1882 for Chronic Joint Diseases. Twelve beds for boys and eight for girls under the age of ten years. Surgeon, Mr. Noble Smith.

MR. THOMAS COOKE'S SCHOOL OF ANATOMY, PHYSIOLOGY, SURGERY, &c.—This school is intended to meet the requirements of three classes of students: 1. Qualified practitioners and advanced students—i.e., gentlemen wishing either to obtain some of the higher qualifications, or to compete for appointments in Her Majesty's Army, Navy, and Indian Medical Service. 2. Students preparing for the usual Primary and Pass Examinations of any of the licensing bodies. 3. Beginners entering upon their medical studies, either by a short term of apprenticeship, or under the new regulations of the Examining Board in England. Both rapid advanced classes, complete in three months or less, but still thoroughly practical, are provided; and also, as required, more elementary classes of six months' duration. The instruction is given on the dissected and undissected body, with normal and pathological specimens, microscopical preparations, chemical, physiological, and surgical apparatus, splints, &c. The operations of surgery are performed by the students on the dead body. Private address: 40, Brunswick-square.

SOUTH LONDON SCHOOL OF PHARMACY.—This school was established in 1868, and removed to the present premises in 1875. Owing to the expiration of the lease at the old premises, it has recently been joined by the analytical and general science teaching branches previously carried on at Kennington-cross, and the whole institution is now consolidated under one roof, so bringing every department under the continuous and direct control of the director, Dr. John Muter, M.A., F.C.S., F.I.C., who personally delivers the lectures on Chemistry, Physics, and Botany, and superintends the laboratory instruction. The department most valuable to medical students is the Medical and General Science Tutorial Department. The subjects taught are:—For Matriculation, &c.: Elementary Chemistry. For First B.Sc. and Preliminary Scientific: Inorganic and Practical Chemistry. For First M.B.: Organic Chemistry, Analysis, and Pharmaceutical Chemistry and Materia Medica. For Apothecaries' Hall and Royal Colleges of Physicians, London and Edinburgh: Chemistry, Botany, and Materia Medica. For Pass M.B. Lond: Practical Toxicology and Forensic Medicine. Students attend by special arrangement, and perpetual or time fees may be had from the Secretary, 325, Kennington-road, London, S.E.

SCHOOL OF PHARMACY OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Lectures on Botany and Materia Medica by Professor Bentley, M.R.C.S. Eng., F.L.S.; Chemistry by Professor Dunstan, F.C.S.; Practical Chemistry, Professor John Attfield, Ph.D., F.R.S., F.I.C., F.C.S., Director of the Laboratories; F. W. Short, Demonstrator; T. J. Eastes, Assistant-Demonstrator; Practical Pharmacy: Joseph Ince, F.L.S. The session commences on Friday, October 1st, at 9 A.M. Medical students, or pupils intending

Digitized by Google

to enter the medical profession, are admitted to the lectures and to a course of practical chemistry of any length in the laboratories. Application for admission to the School, or for further information, may be made to the professors or their assistants in the lecture theatre or laboratories, 17, Bloomsbury-square, London, W.C.

ENGLISH PROVINCIAL HOSPITALS AND MEDICAL SCHOOLS.

BATH ROYAL UNITED HOSPITAL.—120 beds. Honorary Consulting Physician; Dr. Coates. Honorary Physicians: Drs. Goodridge, Cole, and Fox. Honorary Surgeons: Messrs. Stockwell, Fowler, and Freeman. Honorary Medical Officers for Out-patients: Dr. Field, Messrs. Cowan and Craddock. Honorary Assistant-Surgeons: Messrs. Green, Scott, and Ransford. Dental Surgeon: Mr. Gaine. Pathological Registrar and Curator: Mr. H. Culliford-Hopkins. The hospital is recognised by the Royal College of Physicians, Surgeons, &c., and licensed for dissections. It contains a library and an excellent museum, in which are a large number of interesting specimens, both in Pathology and Comparative Anatomy. Fees for attendance—twelve months, £10 10*s.*; six months, £5 5*s.* Instruction in Practical Pharmacy, £5 5*s.* Number of patients admitted during the past year, 1054; out-patients 8256. Operations performed, 156. Anæsthetics recorded, 148. For further particulars, apply to the registrar and curator.

QUEEN'S COLLEGE, BIRMINGHAM.—The Sands Cox Prize, of the value of £20, is offered annually in the Medical Department. It is open to students who have completed their curriculum, and is awarded after examination in Medicine, Surgery, and Midwifery. The examination for this prize in 1886 will be held in the last week in March. Two Ingleby Scholarships will be offered annually after examination in Obstetric Medicine and Surgery, and Diseases of Women and Children. The Scholarships are open to students who have completed the first two years of their curriculum in this College. One or more Sydenham Scholarships will be offered annually, of the value of 30 guineas each. The orphan sons of former students of the Birmingham Medical School have priority of election. No Sydenham scholars are elected whose age exceeds twenty-three years on the day of election. The Scholarships are held for three years, subject to good behaviour. One or more Queen's Scholarships will be offered annually of the value of 30 guineas. They are held for three years, one-third being paid each year, subject to good behaviour. The Russell Memorial Prize is awarded annually after examination in Nervous Diseases. Students of Queen's College are qualified to compete for all scholarships, gold medals, and other prizes offered by the University of London, the Royal College of Surgeons, and the Apothecaries' Society.

GENERAL AND QUEEN'S HOSPITALS, BIRMINGHAM.—*General Hospital.*—Consulting Physician: Dr. Fletcher. Consulting Surgeons: Mr. Crompton and Mr. Baker. Physicians: Drs. Wade, Foster, Rickards, and Saundby. Surgeons: Messrs. Pemberton, Bartleet, Jolly, and Chavasse. Obstetric Officer: Dr. Malins. Assistant-Physicians: Drs. Simon and Foxwell. Assistant-Surgeons: Messrs. Haslam and Barling.—*Queen's Hospital.*—Consulting Obstetric Surgeon: Mr. Berry. Consulting Surgeon: Mr. S. Gamgee. Physicians: Drs. Sawyer, Carter, and Suckling. Surgeons: Messrs. Furneaux Jordan, Wilders, Bennett May, and Lloyd. Obstetric Surgeon: Mr. A. F. Hawkins. Ophthalmic Surgeon: Mr. Priestley Smith. Dental Surgeon: Mr. Charles Sims. Physician for Out-patients: Dr. Hogben. Casualty Surgeons: Messrs. Clay and Marsh.

MASON COLLEGE, BIRMINGHAM.—Founded 1875. Opened 1880. The session will commence on October 1st. Instruction is given in Arts and Science, and students are prepared for the various examinations of the University of London. Entrance and other Scholarships are offered for competition. This College is associated with Queen's College, Birmingham, for the purposes of medical education, all students of the latter College attending in the Physical, Chemical, Botanical, and Physiological Departments of Mason College. The Library contains upwards of 17,000 volumes. A syllabus containing full information as to the various courses of instruction, fees, &c., will be forwarded on application to the Secretary.

BRISTOL SCHOOL OF MEDICINE (affiliated to University College, Bristol).—Students can complete in Bristol the entire course of study required for the Medical and Surgical Degrees of the University of London, and for the Diplomas of the Royal College of Physicians of London, the Royal College of Surgeons of England, the Apothecaries' Society of London, and the Army and Navy Boards. The lectures and instructions given at University College, Bristol, are adapted to the various Preliminary Arts Examinations above referred to, and also to the Matriculation and Preliminary Scientific Examinations of the University of London; while the Medical School, the Royal Infirmary, and the General Hospital together provide for every detail of the professional curriculum required by the University of London and the above examining boards. All necessary information may be obtained from the dean of the Bristol Medical School, Dr. Markham Skerritt.

BRISTOL ROYAL INFIRMARY (instituted 1735).—264 beds. Physicians: Drs. Spencer, Shingleton Smith, Wald, and Shaw. Surgeons: Messrs. Board, Dowson, Prichard, Greig Smith, and Harsant. Ophthalmic Surgeon: Mr. Cross. Assistant-Physician: Dr. Prowse. Assistant-Surgeon: Mr. Paul Bush. House-Surgeon: Mr. Dacre. House-Physician: Dr. Swain. Assistant House-Surgeon: Mr. Thurston. Secretary: Lieut.-Colonel Graham.

Scholarships and Prizes: Two Entrance Scholarships, 35 guineas and 10 guineas, awarded annually in October, after examination in general subjects; Surgical and Medical Suple Gold Medals, 5 guineas each, with 7 guineas added in money; Clarke Prize, 15 guineas; Crosby Leonard Prize, 7 guineas; Tibbitt's Prize, 9 guineas; three Pathological Prizes, 3 guineas each.

Dressers reside in the house in weekly rotation, and have charge of all casualties under the supervision of the house-surgeon. Special instruction (including dresserships) for first-year students in the out-patient department. Class instruction in the wards by the physicians and surgeons on four days a week, in addition to the regular clinical lectures. Clinical Clerkships and Dresserships, 5 guineas for each six months. Special departments for Diseases of Women, the Eye, Ear, &c, with Clerkships and Dresserships attached. A Pathological Clerk is appointed every four months, who performs all post-mortem examinations. The large museum and well-stocked library are arranged and managed for the advantage of students.

Further information can be obtained from Dr. Spencer, Dean of the Faculty.

BRISTOL GENERAL HOSPITAL.—164 beds. Physicians: Drs. Markham Skerritt, Harrison, and Baron. Physician-Accoucheur: Dr. Lawrence. Surgeons: Messrs. Lansdown, Dobson, Keall, and Pickering. Dentist: Mr. Parson. House-Surgeon: Mr. Stephens. Physician's Assistant: Mr. Barker. Assistant House-Surgeon: Mr. Morton. Clinical Clerkship, six months, £5 5*s.* Dresser-ship, six months, £5 5*s.* Obstetric Clerkship, three months, £3 3*s.* Special clinical instruction is given in Diseases of the Skin, Eye, Ear, and Throat, also in Diseases of Women, and in Dental Surgery. Further information may be obtained of the secretary, at the hospital, or from Dr. Markham Skerritt, Dean of the Hospital Faculty.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.—Clinical lectures in Medicine and Surgery in connexion with the Cambridge Medical School are delivered at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery in the wards and out-patients' rooms is given by the physicians and surgeons daily, during the vacations as well as term time. Instruction is also given in all the special modes of medical and surgical investigation. Clinical Clerks and Dressers are selected from students according to merit, and without payment.

DEVON AND EXETER HOSPITAL, Exeter.—Medical and Surgical Staff: Consulting Physician: Dr. Drake. Physicians: Drs. Lewis Shapter and H. Davy. Consulting Surgeons: Messrs. A. Cumming and T. W. Caird. Surgeons: Messrs. Bankart, Harris, Domville, and Bell. House-Surgeon: Dr. Blomfield. The hospital contains 214 beds (including special children's wards). There is a good library, museum, dissecting and post-mortem rooms. Attendance on the practice of this hospital qualifies for all the examining boards. Arrangements can be made by which students can attend Midwifery. For further particulars as to fees, &c., apply to the house-surgeon.

Digitized by Google

WEST OF ENGLAND EYE INFIRMARY, EXETER.—Surgical Staff: Messrs. Bankart and Tosswill. Registrar: Mr. Roper. The Infirmary contains fifty beds. Arrangements can be made for students of the Exeter Hospital to attend the practice of the Eye Infirmary.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, Newcastle-upon-Tyne.—The following Scholarships and Prizes are awarded annually:—A University of Durham Scholarship, value £100, for Proficiency in Arts, awarded to full students in their first year. The Dickinson Scholarship, value £15, and a Gold Medal, for Medicine, Surgery, Midwifery, and Pathology. The Tulloch Scholarship, value £20, for Anatomy, Physiology, and Chemistry. The Charlton Scholarship, value about £35, for Medicine. The Gibb Scholarship, value £25, for Pathology. The Goyder Memorial Scholarship (at the Infirmary), value about £15, for Clinical Medicine and Clinical Surgery. At the end of each session a Silver Medal and Certificates of Honour are awarded in each of the regular classes. Assistant Demonstrators of Anatomy, receiving each an honorarium of £5, two Prosectors, and two Assistant Physiologists are elected yearly. Two Pathological Assistants, two Assistants to the Dental Surgeon, and one Assistant in the Eye Department, are also elected every three months. Medical and Surgical Assistants, Clinical Clerks, and Dressers are appointed every three months.

NEWCASTLE-ON-TYNE INFIRMARY.—Physicians: Drs. Philipson, Drummond, Oliver, and Limont. Surgeons: Drs. Arnison, L. Armstrong, Hume, and Mr. Page. Assistant-Surgeons: Mr. T. A. Dodd and Mr. Williamson. Pathologist: Dr. Drummond. Dental Surgeon: Mr. E. Fothergill. House-Physician: Mr. J. Waldy. House-Surgeon: Dr. G. W. Ridley. The infirmary contains 280 beds. There are special wards for the treatment of Children, and for Ophthalmic and Syphilitic Diseases. Clinical Lectures are delivered by the Physicians and Surgeons in rotation. Pathological Demonstrations are given as opportunity offers by the Pathologist. Practical Midwifery can be studied at the Newcastle Lying-in Hospital, where there is an out-door practice of about 300 cases annually. Lectures are given on Psychological Medicine at the Coxlodge Lunatic Asylum by Dr. R. H. B. Wickham, Medical Superintendent. A Special Course of Instruction is given in the Hospital for Infectious Diseases by the Superintendent and City Officer of Health, Dr. H. E. Armstrong.

GENERAL KENT AND CANTERBURY HOSPITAL.—Open for the reception of patients April 26th, 1793. 48,692 in-patients and 86,963 out-patients have been admitted since the hospital was open. The hospital contains 102 beds. Pupils of the staff are admitted to the practice of the hospital, and have the use of the library of the East Kent and Canterbury Medical Society, for £7 7s. Operation day, Thursday, 11 A.M. Consulting Physician: Dr. Alfred Lochee. Physician: Dr. Henry Alex. Gogarthy. Consulting Surgeon: Mr. James Reid. Surgeons: Messrs. Charles Holttum, Frank Wacher, T. Whitehead Reid, and John Greasley. Dentist: Mr. Martin L. Bell. House-Surgeon: Mr. Z. Prentice. Assistant House-Surgeon and Dispenser: Mr. William P. Barrett. Secretary: Mr. Charles H. Read. Over 700 in-patients, 3000 out-patients, and 1000 dental cases are attended in a year.

LEEDS GENERAL INFIRMARY AND MEDICAL DEPARTMENT OF THE YORKSHIRE COLLEGE.—The Leeds General Infirmary has accommodation for 320 in-patients, surgical and medical, and during the last year 4401 in-patients and 24,600 out-patients were treated; these numbers show a remarkable increase, if compared with statistics of ten years ago, when only 11,500 out-patients were seen. Clinical teaching takes place daily in the wards, and Clinical Lectures are given in the operating-room. There are Medical, Surgical, Ophthalmic, Aural, and Electrical Departments, in each of which special instruction is imparted to students. A Gynæcological and Extern Obstetric Department, together with Laryngeal and Skin Clinics, are being organised. The Public Dispensary, the Fever Hospital, and the West Riding Lunatic Asylum are other medical institutions which are made use of by the Leeds students.

The Leeds Medical School, now the Medical Department of the Yorkshire College, occupies a central position in the town, close to the General Infirmary, and a few minutes' walk from the new buildings of the Science and Art Departments situated in College-road. The present premises were built specially for the purposes of a medical school, and the teaching in purely medical subjects is there given. The teaching in Chemistry and Physics, Practical Chemistry, Practical Toxicology, Biology, and Botany is given in the College-road buildings, the lecture-rooms and laboratories of which are amongst the most commodious in the kingdom. The accommodation for teaching comprises all the conveniences necessary for the various branches of study. All the other courses required by examining boards are given by Professors and Lecturers. The Museums and Library offer special advantages. Several valuable prizes are given at the end of each session. The following appointments at the infirmary are annually open to students:—Resident medical officer, resident surgical officer, resident obstetric officer, appointed for twelve months and eligible for re-election. Two house-physicians, holding office for six months; four house-surgeons, for twelve months; twenty-four physicians' clerks, for three months; twenty-four surgeons' dressers, for six months; eight ophthalmic and aural surgeons' dressers, for three months; eight gynæcological ward clerks, for three months; eight gynæcological out-patient clerks, for three months; twenty-four assistant-physicians' clerks, for three months; twenty-four assistant-surgeons' dressers, for three months; forty-eight dressers in the casualty room, for three months; twelve post-mortem room clerks, for three months.

UNIVERSITY COLLEGE, LIVERPOOL, MEDICAL FACULTY: VICTORIA UNIVERSITY.—The Infirmary attached to the School contains 300 beds, with 40 special beds for the treatment of Diseases of Women. Lock, Lying-in, and Eye and Ear Hospitals are in the immediate vicinity, and their practice is open to the students of the Medical Faculty.

The composition fee for lectures and classes is 60 guineas, which may be paid in two equal instalments with an interval of twelve months; and for hospital practice 40 guineas, which may be paid in the same way.

Two house-physicians and three house-surgeons are appointed from the qualified pupils every six months, also clinical clerks, dressers, and post-mortem clerks.

Two Holt Tutorial Scholarships, each of the value of £100 are awarded annually by the Medical Faculty to senior students. Also an entrance Lyon Jones Scholarship of £21 for two years for students proceeding to the Victoria Degree, and another of the same value, open to all students who have completed their second year. The Derby Exhibition of £15 for Clinical Medicine and Surgery. The Torr and Bligh Gold Medals for Anatomy and Physiology, and the class prizes. During the past year the new Chemical Laboratories have been opened, and the old building added to the Physiological Department. The only changes on the staff are the appointment of Mr. Edgar Browne, as lecturer on ophthalmology, Dr. Hope as lecturer on Hygiene, and Dr. Ross as Demonstrator of Anatomy.

LIVERPOOL NORTHERN HOSPITAL.—150 beds. There is a special ward for the treatment of children. Clinical lectures are delivered by the physicians and surgeons during the summer and winter sessions. Clinical clerkships and dresserships are open to all students without additional fee.

LIVERPOOL ROYAL SOUTHERN HOSPITAL.—Physicians: Drs. Cameron, Carter, and Williams. Surgeons: Messrs. Hamilton, Little, and Paul. Senior House-Surgeon: Dr. F. H. Wigmore. Junior House-Surgeons: Mr J. R. L. Dixon and Mr. W. C. Helme. 200 beds. Clinical Lectures are given by the physicians and surgeons during the winter and summer sessions. Clinical clerkships and dresserships are open to all students. Special wards for accidents and diseases of children. Resident students received.

NORFOLK AND NORWICH HOSPITAL.—150 beds. One year's attendance recognised by examining boards. Fees: For the physicians' practice, 5 guineas for six months. For the surgeons' practice, including dresserships, £10 for three months; £15 for six months; £20 for one year; £30 for two years. Pupils resident and non-resident. Physicians: Sir Peter Eade, Dr. Bateman, and Dr. Taylor. Surgeons: Mr. Cadge, Mr. Crosse, and Mr. Williams. Assistant-Surgeons: Dr. Beverley and Mr. Robinson. House-Surgeon: Mr. H. Chester Nance.

NORTHAMPTON GENERAL INFIRMARY.—Established 1743; rebuilt 1793. In-patients, 1693; out-patients, 8223. Beds,

Digitized by Google

144. Physicians: Dr. Buszard and Dr. Jones. Surgeons: Messrs. G. H. Percival and R. A. Milligan. House-Surgeon: Mr. W. E. Audland. Assistant House-Surgeon: Mr. St. John O. Rands. Out-pupils are received, and have every opportunity of acquiring a practical knowledge of their profession. Instruction is also given in Anatomy and Materia Medica, and Practical Pharmacy. Pupils' fee £25 per annum, or a perpetual fee of £50.

MEDICAL DEPARTMENT OF OWENS COLLEGE, VICTORIA UNIVERSITY.—This medical school is located in a large new building, which forms a part of Owens College. It is provided with a very large dissecting-room, physiological laboratory, private laboratories, and work-rooms, besides lecture-rooms, a museum, and a library. In order to give the fullest possible opportunities for teaching and investigation in the departments of Physiology, Pathology, and Materia Medica, a great extension of the school buildings has been made. The more strictly practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary, to which are attached a fever hospital, a lunatic asylum, and a convalescent home. Medical and surgical clinical classes are conducted in the infirmary by the professors of medicine and surgery, and separate instruction is afforded in the elements of medical and surgical physical diagnosis, in obstetric medicine, ophthalmic surgery, and pathological anatomy by the different members of the staff of the medical school and infirmary. The following scholarships and prizes are open to students of the medical school:—1. A Dauntesey Scholarship of the value of about £100 is offered annually for competition at the beginning of October to persons who have not been students in any medical school in the United Kingdom, and whose age does not then exceed twenty-five years. The subjects of examination are—(*a*) General and Comparative Anatomy; (*b*) Physiological Botany; (*c*) Chemistry; (*d*) Mathematics or Latin. 2. A Scholarship and Prizes are awarded at the end of each academic year to students of the first, second, and third year. 3. A Platt Physiological Scholarship of £50 a year for two years is offered annually to the student who, having studied for one entire session in the physiological laboratory of Owens College, has prosecuted the best original investigation in Physiology, and has passed a satisfactory examination in Physiology. 4. Two Platt Exhibitions of the value of £15 each, to be competed for by first and second years' students in the class of Physiology. 5. A Dumville Surgical Prize of £20 is offered annually for proficiency in Clinical Surgery. 6. Medical and Surgical Clinical Prizes, each of the value of six guineas, are open to competition each year for the best reports (with comments) of cases which have occurred in the wards of the infirmary.

MANCHESTER ROYAL INFIRMARY.—Consulting Physicians: Drs. R. F. Ainsworth, Frank Renaud, H. Browne, and Sir Wm. Roberts. Consulting Surgeons: Mr. Geo. Bowring and Mr. Lund. Physicians: Drs. Henry Simpson, John E. Morgan, D. J. Leech, and J. Dreschfeld. Assistant-Physicians: Drs. James Ross and Graham Steell. Obstetric Physician: Dr. Lloyd Roberts. Surgeons: Messrs. F. A. Heath, Walter Whitehead, Thomas Jones, and James Hardie. Assistant-Surgeons: Messrs. Fred. A. Southam and G. A. Wright. Ophthalmic Surgeon: Dr. D. Little. Dental Surgeon: Mr. G. W. Smith. Resident Medical Officer: Dr. Malcolm Webb. Resident Surgical Officer: Mr. Joseph Collier. Medical Registrar: Dr. J. S. Bury. Surgical Registrar: Mr. W. Thorburn. Pathological Registrar: Dr. Thomas Harris. Assistant Medical Officers: Drs. S. Moritz and A. T. Wilkinson. General Superintendent and Secretary: Mr. W. L. Saunder.

MANCHESTER GENERAL HOSPITAL FOR SICK CHILDREN, Pendlebury and Gartside-street.—The hospital contains 140 beds, including 28 for scarlet fever. The medical staff visit the hospital daily at 10 A.M. Special classes are held for clinical instruction on Saturday afternoons during the winter months. Out-patients are seen daily at 9 A.M. at the dispensary, Gartside-street, Manchester. Physicians: Drs. Ashby and Hutton. Surgeon: Mr. G. A. Wright. During 1885 there were 1220 in-patients and 9649 out-patients under treatment at the dispensary.

RADCLIFFE INFIRMARY, OXFORD.—This infirmary is open to students for Medical and Surgical work in the wards and out-patients' departments. Clinical lectures are given by the Litchfield Clinical Lecturer in Medicine and Surgery. Also tutorial instruction and demonstrations are given in special Regional Anatomy (medical and surgical), methods of Medical Diagnosis and Surgical Manipulation. The whole course of study at the museum and infirmary combined is intended for students until they have passed the Second Conjoint Examination, or the 1st Oxford M.B.

SHEFFIELD SCHOOL OF MEDICINE.—The Infirmary contains 180 beds, a Museum of Pathology, Library, and Post-mortem Theatre, with microscopes and all the appliances for clinical research. Perpetual fee for attendance on all the lectures required by the Royal College of Surgeons and the Apothecaries' Hall, £45. A tutor's fee of £2 2*s.* is required from students entering for Anatomy and Physiology.

JESSOP HOSPITAL FOR WOMEN, Gell-street, Sheffield.—Hon. Acting Medical Officers: Dr. Keeling, Mr. F. Woolhouse, Mr. R. Favell, and Mr. A. H. Laver. The hospital is devoted to Diseases peculiar to Women. There is also an Obstetric Department for the admission of a small number of cases. A staff of midwives connected with the hospital attend lying-in women at their own homes, and in case of need are assisted by the members of the medical staff. Out-patients are attended daily. Students can attend the practice of the Hospital, and be supplied with cases of midwifery. House-Surgeon: J. M. Willey. Secretary, H. B. Warner, 39, George-street.

NORTH STAFFORDSHIRE INFIRMARY, Hartshill.—The New Infirmary, opened in 1869, is built on the pavilion plan, has accommodation for over 200 patients, including children's wards, and special ovarian wards. In-patients last year, 1660; out-patients, 9299. The attendance of pupils at this infirmary is duly recognised by all the examining boards; and there are unusual facilities for acquiring a practical knowledge of the profession. Physicians and Medical Officers: Drs. J. T. Arlidge and C. Orton, and Messrs. Ashwell and J. G. West. Surgeons: Messrs. W. H. Folker, J. Alcock, and W. D. Spanton. Dental Surgeon: Mr. A. W. Whittingham. Secretary: Mr. R. Hordley, Hartshill, Stoke-on-Trent, from whom particulars as to fees &c. may be obtained.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Founded 1848. Beds, 224. A preparatory school of Medicine and Surgery. The pupils have the advantage of seeing the whole of the practice of the physicians and surgeons, and are trained in clinical work by the medical and surgical staff. The attendance of pupils at this hospital is recognised by all the examining boards. Operations are performed every Thursday at 11 o'clock, and practitioners are welcomed.

YORK COUNTY HOSPITAL.—Established 1740; rebuilt 1851. 116 beds. In-patients, 948; Out-patients, 6383. Consulting Physician: Dr. W. Matterson. Physicians: R. Turner, M.B., and R. Petch, M.B. Consulting Surgeon: Mr. W. D. Husband. Surgeons: Messrs. R. Hewetson, W. H. Jalland, and F. Shann. Dental Surgeon: Mr. W. Glaisby. House-Surgeon: Mr. E. F. Morris. Assistant House-Surgeon: Mr. Thomas Burt. Secretary: Mr. R. Holtby.

SCOTTISH HOSPITALS AND MEDICAL SCHOOLS.

SCHOOL OF MEDICINE, EDINBURGH.—The lectures qualify for the University of Edinburgh and the other universities; the Royal Colleges of Physicians and Surgeons of Edinburgh, London and Dublin, and the other Medical and Public Boards. In accordance with the Statutes of the University of Edinburgh, any four of the medical classes required for graduation, or two complete *anni medici*, may be attended in this school, each of which *anni medici* may be constituted by attendance on two of the six months' courses, or on one of these and two three months' courses. The regulations require that the fee for any class, taken for graduation in Edinburgh, shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this school.

Fees.—For a first course of lectures, £3 5*s.*; for a second, £2 4*s.*; perpetual, £5 5*s.* To those who have already attended a first course in Edinburgh the perpetual fee is £2 4*s.* Practical Anatomy (six months' course), £3 3*s.*; course of demonstrations, £2 2*s.*; perpetual, £4 4*s.* Practical Anatomy with course of demonstrations, £4 4*s.* Practical

Digitized by Google

Chemistry, £3 3s. Analytical Chemistry, £2 a month, £5 for three months, or £10 for six months. Practical Materia Medica, including Practical Pharmacy, Diseases of the Ear, Diseases of the Skin, Diseases of Children, and Diseases of the Tropics and Climatology, each £2 2s. Vaccination, £1 1s. For summer courses of Clinical Surgery and Clinical Medicine, each £2 4s.; Practical Anatomy, including Anatomical Demonstrations, Operative Surgery, and Practical Medicine and Medical Diagnosis, each £2 2s. Insanity, £1 1s.

EDINBURGH SCHOOL OF MEDICINE AND PHARMACY, Marshall-street, Nicolson-square.—The classes of this school will be resumed for the winter session on Oct. 19th. Chemistry, Midwifery, Surgery, and Medicine. From the Dispensary attached to this institution, Pharmacy, Practical and Theoretical, Practical Midwifery. Out-door Practice, Medical and Surgical Diagnosis. Attendance at this institution qualifies for the University of Edinburgh and all other licensing boards. Tutorial classes in all the branches of the medical curriculum. Preliminary Medical Classes, 11 A.M. to 4 P.M., and in the evening; Theoretical Chemistry, 10 to 11 A.M.; Theoretical Midwifery, Dr. C. Bell, 11 to 12 A.M.; Theoretical Pharmacy, R. Urquhart, 3 to 4 P.M.; Class for Medical Diagnosis, 2 to 3 P.M.; Class for Surgical Diagnosis, 3 to 4 P.M. Practical Midwifery and Out-door Practice at the Edinburgh Provident Dispensary, 2 to 4 P.M., under the supervision of Drs. Bell, Robertson, Wylie, Matheson, Jamieson, and Price; Practical Pharmacy, 2 to 4 and 7 to 8 P.M.; Practical and Analytical Chemistry, 9 A.M. to 5 P.M. The Pharmaceutical Section of this School will open on Oct. 4th. Particulars of R. Urquhart, Secretary.

ROYAL INFIRMARY, EDINBURGH.—Beds are set apart for clinical instruction by the professors of the University of Edinburgh. Courses of Clinical Medicine and Surgery are also given by the ordinary physicians and surgeons. Special instruction is given in the medical department on Diseases of Women, Physical Diagnosis, and on Diseases of the Skin; and in the surgical department on Diseases of the Eye, the Ear, and Larynx. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, also to cases of Incidental Delirium or Insanity. Post-mortem examinations are conducted in the anatomical theatre by the pathologists, who also give practical instruction in Pathological Anatomy and Histology. The fees for hospital attendance are as follows—viz.: Perpetual ticket, in one payment, £12; annual ticket, £6 6s.; six months, £4 4s.; three months, £2 2s.; monthly, £1 2s. Separate payments amounting to £12 12s. entitle the student to a perpetual ticket. No fees are paid for any medical or surgical appointment. The appointments are as follows:—1. Resident physicians and surgeons are appointed, and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Special non-resident clerks are appointed for six months. The appointment may be renewed for a like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the pathological department are appointed by the pathologists.

ANDERSON'S COLLEGE, GLASGOW.—The following courses are given, which qualify for all the licensing boards:—In winter: Anatomy, Chemistry, Physiology, Surgery, Medicine, Materia Medica, &c. In summer: Midwifery, Medical Jurisprudence, Botany, Hygiene, &c. The Chemical Laboratory is open daily from 10 to 5. Students of the College are admitted to the practice of the Ophthalmic Institution on payment of a matriculation fee of 5s.

Fees.—Each course of lectures (except Anatomy), first session, £2 2s.; second session, £1 1s.; afterwards free. Anatomy (including dissecting-room), first session, £4 4s.; second session, £4 4s.; third session and perpetual, £1 1s.; summer (including Practical Anatomy), £1 11s. 6d. Practical Anatomy only, £1 1s.; Osteology, £1 1s. Students who have attended classes at other schools will be admitted to such classes as they may have attended elsewhere at reduced fees. Fees for all the Lectures and Hospital Practice required of candidates for the diplomas of Physician and Surgeon, £48.

GLASGOW ROYAL INFIRMARY SCHOOL OF MEDICINE.—The winter session will open on October 26th. Courses of lectures are given on all the subjects required by the licensing bodies for qualification, and lectures and demonstrations are also given on Public Health, Practical Physiology, Operative Surgery, Aural Surgery, Dental Surgery, Diseases of the Eye, and of the Throat and Nose. During summer lectures on Insanity are given by Dr. A. Robertson, in the City Asylum under his charge.

Class Fees.—For each course, first session, £2 2s.; second session, and perpetual, £1 1s. Anatomy: First winter session, £4 4s.; summer session, £1 11s. 6d.; second winter session, £4 4s.; afterwards the fee for lectures and practical anatomy is £1 11s. 6d. per session. Lectures on Diseases of the Ear, £1 1s.; with clinique to those not students of the hospital, £2 2s. Dental Dispensary free to students of the hospital; to others, £5; first year, perpetual, £10. Lectures on the Eye, £1 1s.; other special courses free.

GLASGOW ROYAL INFIRMARY.—Number of beds, 542. In addition to the ordinary medical and surgical wards, there are separate wards for the treatment of Venereal Diseases and the Diseases of Women, whilst Diseases of the Skin, Eye, Ear, Throat, and Teeth are specially treated at the Dispensary. Courses of Clinical Medicine and Surgery are given by the physicians and surgeons; instruction in Pathological Anatomy and Histology is given by the pathologist.

Appointments.—There are four physicians' and six surgeons' assistants. These appointments are free, and can be held for twelve months; they are open to students who have passed all their examinations except the last, or to gentlemen who have a qualification in medicine or surgery. Clinical assistants, dressers, dispensary clerks, and pathological assistants are selected from the students without additional fee.

Fees for Hospital Practice and Clinical Lectures.—First year, £10 10s.; second year, £10 10s.; afterwards free. For six months, £6 6s.; three months, £4 4s. Vaccination certificates, £1 1s.

GLASGOW HOSPITAL AND DISPENSARY FOR THE DISEASES OF THE EAR, 28, Elmbank-crescent.—The hospital, which contains twelve beds for in-door patients, is always open for urgent cases. Hours of surgeons' visits, 2 P.M. daily; clinical teaching daily. Out-patients are seen on Mondays, Tuesdays, Thursdays, and Fridays, at 2 P.M., by Dr. Barr and assistants; and operations and special demonstrations to students and practitioners take place on Thursdays from 3 to 4 P.M. Adam Sutherland, 75, West Nile-street, Secretary.

GLASGOW WESTERN MEDICAL SCHOOL, University-avenue, Hillhead.—The winter session will open on October 26th. The school is situated close to the Western Infirmary, where students obtain their Hospital Practice and Clinical Lectures. To accommodate the increasing number of students, the dissecting rooms (during the vacation) have been entirely rearranged and enlarged. The attention of students is directed to the unusual facilities presented for the study of Practical Anatomy and Operative Surgery, the supply of subjects being practically unlimited. The dissecting-rooms are open for work from the beginning of October till the end of July.

The lectures qualify for the University of Glasgow in accordance with the regulations, the Faculty of Physicians and Surgeons, Glasgow, and the other corporations.

Class Fees.—For each course of lectures, first session, £2 2s.; second session, £1 1s. Students who have attended a first course elsewhere pay £1 1s. Anatomy, including Practical Anatomy, £4 4s. Summer session, £1 11s. 6d.

GLASGOW WESTERN INFIRMARY.—This hospital adjoins the University of Glasgow. Number of beds upwards of 400. Special wards are set apart for Diseases of Women and for Cutaneous Affections. In the out-patient department there are special cliniques for Diseases of Women and for Diseases of the Throat, Ear, and Teeth. The Clinical Courses are given by the Physicians and Surgeons, each of whom conducts a separate class, and students may attend whichever they select at the beginning of the session. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological Department a systematic course is given in the winter and a practical course in the summer; these are likewise recognised by the University for graduation. Eight resident assistants are appointed annually, without salary, from those who have completed their course. The fee for the hospital practice, including the various courses of clinical instruction, is 20 guineas in one payment, or in two equal instalments for the first and second years; for six months, 7 guineas; and for three months, 4 guineas. Secretary: Henry Johnston, 125, Buchanan-street, Glasgow.

Digitized by Google

GLASGOW HOSPITAL FOR SICK CHILDREN, situated at Garnet-hill, was opened in December, 1882, and is now available to medical students for clinical instruction in the diseases peculiar to childhood. The hospital includes 57 beds for non-infectious cases only.

GLASGOW OPHTHALMIC INSTITUTION, 126, West Regent-street.—40 beds. Clinical and systematic course of lectures for students during the winter and summer sessions.

ABERDEEN ROYAL INFIRMARY.—Contains about 250 beds. Consulting Physician: Dr. A. Harvey. Physicians: Drs. J. W. F. Smith-Shand, R. Beveridge, and Angus Fraser. Surgeons: Messrs. A. Ogston, Ogilvie, J. O. Will, and R. J. Garden. Ophthalmic Surgeon: Dr. Alex D. Davidson. Dental Surgeon: Dr. Williamson. Resident Superintendent and Apothecary: Dr. T. Collins. Treasurer and Secretary: Mr. W. Carnie.

ABERDEEN ROYAL LUNATIC ASYLUM.—Contains about 580 beds. Consulting Physician: Dr. Robert Jamieson. Clinical instruction is given to students during three months in summer.

IRISH HOSPITALS AND MEDICAL SCHOOLS.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Belfast.—Eight Junior Scholarships have been founded in the Faculty of Medicine, of the annual value of £25 each. Two are tenable by Matriculated Students, commencing the first, second, third, and fourth year of their course respectively. The Examinations for Junior Scholarships of the second and third years in the Faculty of Medicine take place at the commencement of the second and third year of their medical course. Matriculated Students in Medicine intending to compete for Medical Scholarships of the second year must be of not more than one year's standing as Students of Medicine, and must have attended, in some of the Queen's Colleges or in a University capable of granting degrees in Medicine, two at least of the following courses—viz.: Chemistry, Botany and Zoology, Anatomy and Physiology, Materia Medica and Pharmacy, Practical Chemistry, Practical Anatomy. Matriculated Students in Medicine intending to compete for Medical Scholarships of the third year must be of two years' standing and not more, and must have attended, in some of the Queen's Colleges or in a University capable of granting degrees in Medicine, four at least of the following courses—viz: Chemistry, Botany and Zoology, Anatomy and Physiology, Materia Medica and Pharmacy, Practical Chemistry, Practical Anatomy. Matriculated Students in Medicine intending to compete for Medical Scholarships of the fourth year must be of three years' standing and not more, and must, in addition to the qualifications prescribed above, have attended, in their third year, two at least of the following courses—viz.: Theory and Practice of Medicine, Theory and Practice of Surgery, Midwifery, and Diseases of Women and Children.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Cork.—The building is provided with a very large, well-ventilated dissecting room, with physiological and toxicological laboratories, materia medica, anatomical and pathological museums, as well as a room for surgical and obstetrical instruments and appliances. There are well-appointed physical and chemical laboratories, and a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden. The plant houses are now completed and well filled with plants, and are open to the students in the class of Botany.

Fees.—For Practical Anatomy and for Practical Chemistry, £3 each course; for Anatomy and Physiology, £3 first course, and £2 for each subsequent course. Other medical classes, £2 first course, and £1 each subsequent course. Eight scholarships (value about £30 each), as well as several exhibitions and class prizes, are awarded every year.

SIR PATRICK DUN'S HOSPITAL, Dublin (in connexion with the School of Physic).—The payment of £3 3*s.* to the hospital entitles any student to attend the clinic of the hospital for twelve months, and to attend the lectures delivered by the University Lecturer in Operative Surgery. Students who have taken out the degrees of Bachelor in Medicine and Master in Surgery in Trinity College are entitled to attend the hospital as perpetual free pupils.

Clinical Lectures are delivered in the hospital theatre at 10 o'clock on Mondays and Tuesdays. In addition to the hospital fee, the payment of a fee of £9 9*s.* is required for the privilege of attending these lectures. Total fees for hospital and lectures for twelve months, £12 12*s.*

Sir Patrick Dun's Maternity.—Total fees for college students, £3 3*s.* Total fees for externs, £6 6*s.*

THE ADELAIDE MEDICAL AND SURGICAL HOSPITALS, Peter-street, Dublin.—Fee for nine months' hospital attendance £12 12*s.*; six months', £8 8*s.* Summer, three months', £5 5*s.*

Three resident pupils are selected half-yearly. At the termination of the session, prizes in Clinical Medicine and Surgery, in Obstetric Medicine, and in Ophthalmic Surgery, will be awarded.

Hudson Scholarship.—In addition to the junior prizes, the Hudson Scholarship, £30 and a gold medal, as well as a prize of £10, together with a silver medal, will be awarded at the end of the session for proficiency in Clinical Medicine and Medical Pathology, Clinical Surgery and Surgical Pathology, Pathological Histology, Surgical Appliances, including instruments and bandaging, Ophthalmology, and Gynæcology.

The certificates of attendance are recognised by all the universities and licensing bodies in the United Kingdom.

LEDWICH SCHOOL OF SURGERY AND MEDICINE, Peter-street, Dublin (formerly original School of Anatomy, Medicine, and Surgery).—There are endowments in favour of students, subject to conditions prescribed by the founder, in the following departments:—Two in Anatomy and Physiology; two in Minute Anatomy; two in Practical Anatomy; one in Surgery. Certificates of attendance on these lectures are received by the various examining boards; by the Apothecaries' Halls of Dublin and London; by the King and Queen's College of Physicians in Ireland; by the Royal Colleges of Physicians, London and Edinburgh; by the Royal University, the Universities of Dublin, London, and Glasgow; by the Glasgow Faculty of Physicians and Surgeons; and by the Queen's University in Ireland. The Senate of the Royal University having recognised the lectures of this school, arrangements have been made to educate students for its Medical and Surgical Degrees in accordance with its requirements. This school is in a central situation, and is replete with every convenience for study and successful instruction. By its teachers it is connected with nine hospitals, four of which are Medical and Surgical hospitals, one for Fever, one for Midwifery and Diseases of Women and Children, one for Diseases of the Eye and Ear, &c.

Returns for the session 1886-7 have not been received from this school.

CARMICHAEL COLLEGE, Aungier-street, Dublin.—The following scholarships, &c., are awarded to students entering for an *annus medicus* for the current year:—The Carmichael Scholarship, value £15; the Maine Scholarship, value £15; also Lecture Prizes, value £3 and £2 each, £97 being given annually in prizes.

DR. STEEVENS'S HOSPITAL.—This hospital, containing beds for 250 patients, is situated close to the Kingsbridge Terminus of the Great Southern and Western Railway, occupying a position in the centre of one of the busiest manufacturing districts of the city, otherwise unprovided with medical institutions. Immediately adjoining is St. Patrick's (Swift's) Asylum for the Insane. The hospital is easily accessible by two lines of tramways, and owing to its position affords exceptional advantages for clinical instruction. There is a ward entirely devoted to Syphilitic Disease, a detached building for Fever cases, and an extensive Out-patient Department, with separate Clinics for Diseases of the Skin, Throat, Teeth, and those peculiar to Women.

The hospital is visited daily at 8.30 A.M. by the resident surgeon, and at 9 A.M. by the physicians and surgeons. The surgical wards are also visited each evening. Clinical Lectures are given by the physicians and surgeons during the session. There is accommodation in the hospital for two medical and six surgical resident clinical assistants, who, in addition to their rooms and furniture, are provided with coals and gas.

Fees.—Hospital Practice: Nine months, £12 12*s.*; six months, £8 8*s.*; three months, £5 5*s.* Dressership: Winter, six months, £21; summer, do., £15 15*s.*

MATER MISERICORDIÆ HOSPITAL, Dublin.—This hospital contains 230 beds, 50 beds being specially reserved for patients suffering from fever and other contagious diseases. Two Clinical Lectures will be delivered in each week, in

Digitized by Google

addition to the daily bedside instruction. A special course of lectures on Fever will be given. A certificate of attendance upon this course, to meet the requirements of the King and Queen's College of Physicians, may be obtained. A ward has been assigned for the treatment of Ophthalmic Diseases. Opportunities are afforded for the study of Diseases of Women in the ward under the care of the Obstetric Physician, and at the dispensary held on Wednesdays and Fridays during the session. Lectures on Clinical Gynæcology will be delivered on Wednesdays. "Leonard Prizes" (Clinical): Prizes of the value of £30 will be given at the end of the winter session, in accordance with the directions contained in the will of the late Mark Leonard, Esq. Certificates of attendance upon this hospital are recognised by the Royal University and all the licensing bodies in the United Kingdom.

Fees.—Nine months, £12 12*s.*; six winter months, £8 8*s.*; three summer months, £5 5*s.*

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS, North Brunswick-street, Dublin.—These hospitals contain 312 beds—110 for Surgical cases, 82 for Medical cases, and 120 for Fever and other epidemic diseases.

There will be a distinct course of Lectures and Clinical Instruction in Fevers. Operations are performed on Monday and Wednesday mornings, except in cases of emergency. A course of Practical Instruction in Ophthalmic Surgery will be given. Fee for the certificate, £3 3*s.*

A Resident Surgeon is appointed every alternate year, receives a salary, and holds office for two years. Eight Resident Clinical Clerks are appointed each half-year, and provided with furnished apartments, fuel, &c. These appointments are open not only to advanced students, as formerly, but also to those who are qualified in Medicine or Surgery. Dressers are selected from among the best qualified of the pupils, without the payment of additional fee.

COOMBE LYING-IN HOSPITAL, AND GUINNESS DISPENSARY FOR THE TREATMENT OF DISEASES PECULIAR TO WOMEN.—The hospital contains 65 beds, and has also a large extern maternity attached. Nearly 3000 confinements are attended annually by the pupils of the hospital. A special dispensary for diseases peculiar to women is held daily, and clinical instruction given. The certificates of the hospital are recognised by all licensing bodies, and its diploma is accepted by the Local Government Board, &c. Further particulars can be learned from the master at the hospital.

ROTUNDA HOSPITAL, Rutland-square, Dublin.—This institution consists of two distinct hospitals—namely, the Lying-in Hospital and the Auxiliary Hospital, the latter for the reception of patients suffering from Uterine and Ovarian Diseases. There is also a large extern maternity in connexion with the hospital, and a dispensary for Diseases peculiar to Women, which is open daily. Clinical instruction is given daily (Saturdays excepted), in Midwifery and he Diseases peculiar to Women, special attention being directed to the application of antiseptics in midwifery, and lectures on these subjects are delivered regularly throughout the session. Accommodation is provided for a limited number of intern pupils.

MEDICAL TEACHERS.

Dr. ABBOTT attends daily from 11 A.M. to 2 P.M. for the treatment of Stammering, Stuttering, &c.—61, Margaret-street, Cavendish-square, W.

Dr. ALTSCHUL has made Stuttering, Lisping, Falsetto, recent or of long standing, due to Nervousness, &c., irrespective of age or sex (without any mechanical appliances), his special, life-long study. The voice developed and strengthened.—9, Old Bond-street, W.; and at Brighton and Hastings.

Messrs. BAILLY and COATES prepare candidates for Matriculation, Apothecaries' Hall, College of Preceptors, and all other English, Scotch, and Irish Medical Preliminary Examinations.—30-32, Ludgate-hill, E.C.

Mr. J. BECKTON, C.M., prepares candidates for the London Matriculation, Medical and Law Preliminary, University, Local, and other Examinations. Boarders received.—41, Torrington-square, W.C.

Messrs. BOSWORTH and STERN prepare for Preliminary Medical, First B.Sc.. &c.—Kenmore, Putney, S.W.

Mr. L. BRYAN, M.A. Cantab., continues for the thirteenth year his most successful preparation of resident and non-resident students for Matriculation and the Medical Preliminaries. Students entering at any of the hospitals are taken as boarders and receive careful supervision, every home comfort, and assistance in their professional studies.—140, Gower-street, W.C.

Mr. H. CRASSWELLER, B.A., prepares candidates for Medical and Law Preliminaries and Matriculation.—12, Aberdeen-park-road, Highbury, N.

Mr. A. H. DAWES, 1st B.A. Lond., gives lessons privately, in class or by post, in preparation for the London Matriculation and Medical Preliminary Examinations.—Adderstone, Vardens-road, New Wandsworth (close to Clapham Junction Station).

Dr. EBERLE (Thirsk, Yorks.), late Principal of the Easingwold Medical College, Author of "Students' Medicine," &c. &c.—Gentlemen prepared for the Preliminary Examination in Arts of the Universities, any of the Professions and Services, also for the Primary, Pass, and Competitive Examinations. Personal and special attention directed to the assistance of Practitioners, Assistants, and others, by letter.

Mr. S. ELLIOTT, B.A. Lond., prepares for Matriculation and Degree Examinations, Law, Medical, and other Preliminaries.—Emery Hill's Hospital, Rochester-row, S.W. (near Victoria Station).

Mr. J. GIBSON, M.A., prepares candidates for the London Matriculation, and Preliminary Medical and Legal Examinations.—Quernmore, Bromley, Kent.

Mr. THOMAS LYLE, M.A., F.R.Hist.S., of the London and Dublin Universities, prepares gentlemen, resident and non-resident, for the various Preliminary Arts Examinations and Matriculation at the London University.—Grove House, Shacklewell-lane, London, N.E.

Dr. MAYBURY prepares candidates for all Medical and Science Examinations.—19, Bloomsbury-square, W.C.

Mr. PIESSE prepares candidates in Materia Medica, Botany, Pharmacy, and Chemical Physics.—Savoy House, 115, Strand, W.C.

Mr. J. W. SAUNDERS, A.P.S., G.S.T., prepares gentlemen for Examination in Anatomy, Physiology, Botany, Chemistry, Materia Medica, Pharmacy, &c.—6, Rochester-square (late Camden-road), N.W.

Mr. H. SERGEANT, B.A. Lond., holds special classes for London University Matriculation, the Preliminary Medical Examinations, &c.—8, High-street, Camden-town, N.W.

Mr. BUTLER SMITH assists pupils in reading up for the London Matriculation, and Legal, Medical, and Pharmaceutical Examinations.—Polytechnic, Regent-street, W.

Mr. H. WAITE prepares pupils for Matriculation, Preliminary Scientific, and the Examinations for Medical Registration of all the licensing bodies.—342, Strand, W.C.

Mr. F. A. WHITE, B.A., prepares candidates for Matriculation and Medical and Legal Preliminary Examinations.—92, Richmond-road, Bayswater, W.

Mr. MAURICE WILLIAMS prepares candidates for Examination in Theoretical and Practical Chemistry, Materia Medica, &c.—The City School of Chemistry, 27, Chancery-lane, W.C.

Mr. J. WOODLAND, F.L.S., F.C.S., holds classes and demonstrations in Practical and Theoretical Chemistry, Chemical Physics, Materia Medica, and Pharmacy; in the Botanical classes specimens are supplied to each student, and all apparatus is found for the Practical Chemistry course. These classes are held for candidates for the Primary L.R.C.P., L.S.A., and the M.B. degree of the different Universities, at the Central School of Chemistry.—173, Marylebone-road, N.W.

To Correspondents.

WE tender our best thanks to those gentlemen who have kindly supplied us with the returns and prospectuses upon which the information given in this Students' Number of THE LANCET relative to the various medical examining bodies, hospitals, and medical schools of the United Kingdom is based.

The present number being principally devoted to information especially interesting to students, we are necessarily compelled to defer the publication of communications on other important subjects.

TERMS OF SUBSCRIPTION TO THE LANCET.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year ..... £1 12 6 | Six Months..... £0 16 3
TO CHINA AND INDIA ..... One Year 1 16 10
TO THE CONTINENT, COLONIES, AND UNITED STATES ..... Ditto 1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

Funeral

OF THE LATE

JAMES G. WAKLEY, M.D.

THE funeral of the late Editor of THE LANCET took place on Saturday afternoon last, the 4th inst., at the Cemetery of Chobham Parish Church. For the past quarter of a century the name of Dr. James G. Wakley has been intimately associated with this Journal, and now that the last tribute of affection and esteem has been paid him, and the grave has closed over his remains in the spot that he had himself selected for their last resting-place, we feel that an affectionate record of the event should find a place in these pages. The funeral was very numerously attended by his relatives, by representatives of his editorial staff, by members of the medical profession, and by friends and sympathisers. As one approached his residence the signs of a respectful observance of the occasion were plainly discernible in the country around; but it was not until the funeral *cortège* left the house, with the coffin covered by floral wreaths and designs, followed by a long line of carriages, that any adequate notion could be realised of the respect and esteem in which he was held. All the shops and cottages along the route manifested tokens of mourning, even the public-houses being closed. The churchyard was full of country people of all ages from the parishes in its vicinity. There were old men and women, maidens and children, poor enough for the most part, but not too poor to have provided themselves with something in the shape of mourning to mark their respect for the friend and neighbour they had lost. As soon as all had passed into the little church and a brief interval was allowed for quietude, the funeral service commenced. It was conducted by the Rev. T. Stirling Coles, M.A., assisted by the Vicar of Chobham, the Hon. and Rev. H. J. Acworth, who had kindly granted permission to Mr. Coles, an old and valued friend of the late Dr. Wakley, to perform the service.

This part of the ceremony over, the body was borne to the cemetery hard by. The attendance at the grave was very large, made up, as we have said, for the most part of the villagers, among whom the late Dr. Wakley had spent so many years of his life, and to whom he had evidently endeared himself by his numerous acts of unostentatious benevolence and charity. After the sublime sentences of that service with which it is the lot of few indeed not to be acquainted, a hymn was sung, in which all present joined. We feel sure that it was just as our friend would have desired. To die amongst those we love, to be buried in the midst of scenes that were once so familiar, and to be followed to the grave by the poor, the aged, and the village children, about the sincerity of whose regret there could be no suspicion—what could be better?

The following gentlemen, amongst others, were present at the funeral:—Mr. Wakley, Mr. H. Membury Wakley, Mr. T. Wakley, jun., Mr. S. Potter, Mr. H. Sandford, Mr. Tweedy, F.R.C.S., Dr. J. A. Marston, Dr. J. G. Glover, Mr. J. G. Barford, Mr. A. J. Pepper, F.R.C.S., Dr. A. Money, Dr. T. Graham Balfour, F.R.S., Mr. Henry Power, F.R.C.S., Sir William Dalby, Dr. John Williams, Dr. Coupland, Dr. C. H. Ralfe, Mr. Henry Smith, F.R.C.S., Mr. W. H. Battle, F.R.C.S., Mr. Shirley Murphy, Mr. Wellington Lake, Mr. W. Scott Thomson, Dr. Hope, Mr. T. Stone, Mr. Braybrooke, Mr. E. Marshall, Mr. Sharp, Mr. Ralph Atkinson, Mr. J. McKee, Mr. Stanley Alder; Mr. J. J. Croft and Mr. W. H. Strange representing respectively the publishing and advertising departments of THE LANCET, and Mr. Fitzsimmons and Mr. Trotter, Mr. Hermon, and Mr. Pennet, the printing, reading, and machining departments. Mr. R. A. Owthwaite also attended, at the wish of the Lord Mayor, to represent the Council of the Metropolitan Hospital Sunday Fund. Very many wrote expressing regret at their unavoidable absence.

On the evening of the 5th inst., the Rev. T. S. Coles, M.A., taking his text from Isaiah (chap. xxx., v. 18), after some preliminary words, made the following observations relating to Dr. Wakley:—

"And now it is time for me to make some remarks about him over whom the grave closed yesterday with solemnity and honour. In many senses our departed friend may be called a public character. He was a principal founder of the London Hospital Sunday; he was Editor of the leading medical journal, THE LANCET, and, aided by his staff, he called attention to and contributed to improve the sanitary condition of several of our large towns. It is not of these, however, we now speak, but as he is personally known throughout this parish by his familiar form and acts. He was a man of quick sensibility, and gifted with wide sympathies, especially in want and distress. I have had many occasions for naming those who stood in need of help, and I never knew an instance in which he withheld succour. His ear was attent, and he had a hand 'open as day for melting charity.' His liberality, great at all times, was markedly so at Christmas, in the munificent distribution of gifts amongst all his poorer neighbours. If tears are the distillation of the heart, these will flow plentifully from many eyes in the freshness of his memory. Yet he had a higher aim, the spiritual benefit of the surrounding poor, and of others at a distance. For this end he might be frequently found in the abodes of indigence and suffering, with an open Bible and on bended knees.

"And this, we believe, was the reflex of his own mental and spiritual state. Until failing health forbade, whoever else was absent from the evening service of this church, he never was. Evangelical worship accorded with his taste and his perception of what was acceptable to God. He reverenced Holy Scripture, and he carefully excluded from the columns of his Journal whatever appeared to militate against its authority and inspiration. He became an anxious inquirer after truth. He knew that he was attacked by a fatal disease, and as the shadows of the evening of his days lengthened, his active mind became concentrated upon the realities of the eternal world. His sense of sin, with abhorrence and confession of it, deepened. His faith was simple, his humility conspicuous; his patience and resignation to the will of God was enduring, and his thoughtfulness for others unmistakable. A threefold element of his character may be summed up in an Apostle's words: 'Not slothful in business, fervent in spirit, serving the Lord.'

> 'This spirit shall return to Him
> Who gave its heavenly spark,
> Yet think not, Sun, it shall be dim
> When thou thyself art dark.
>
> 'No! It shall live again and shine
> In bliss unknown to beams of thine,
> By Him recalled to breath,
> Who captive led captivity,
> Who robbed the grave of victory,
> And took the sting from death.'

Yet the best examples will fail if they are not made practical. Referring to our text, observe that waiting is a posture, not permanent, but temporary. We wait only until the desire is accomplished or final disappointment is decisive. God is the sanctuary of His people, and to watch His eye with steadfast gaze is the best mode of sustaining the spirit in the posture of waiting. And so a voice comes to us from the grave to-day. It tells of admonition, of warning, of encouragement. May the Holy Spirit make it effectual and seal souls in this congregation, as we trust He has done for our departed brother, unto the day of redemption! Amen."

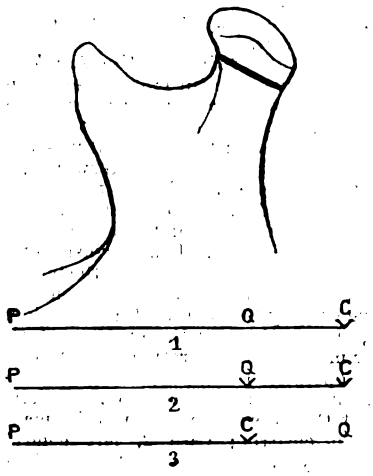
Clinical Remarks

ON

EXCISION OF THE CONDYLE OF THE LOWER JAW FOR THE RELIEF OF MECHANICAL TRISMUS.



BY RICHARD DAVY, M.B., F.R.S.E.,
SURGEON TO THE WESTMINSTER HOSPITAL.

GENTLEMEN,—In 1878 I read a paper before the Association of Surgeons practising Dental Surgery on the subject of excision of the condyle of the lower jaw for trismus. I have now operated on three cases; so will relate briefly the three histories, and then point out why this operation has been performed, and with what results.

CASE 1.—Sarah C——, aged fifty, married, was admitted into Westminster Hospital on Oct. 23rd, 1878, suffering from inability to open her lower jaw by reason of fixity of the temporo-maxillary joint on the left side. In June, 1877, she was much exposed to cold, and for toothache had her left first molar extracted. In August an abscess formed, causing great deformity of her left cheek. In September the abscess burst into her mouth of its own accord, and nearly half a pint of fetid pus was discharged. The abscess cavity slowly healed, but she noticed an increasing difficulty in opening her mouth wide, some thickness of speech, and an occasional spasm of the left angle of the mouth. The trismus has steadily got worse. The patient has been married for twelve years without having been pregnant. She has been treated in St. Thomas's Hospital by a 21b. sandbag hung on to her lower jaw, but without any good result. On admission her speech was thick, and she could only pass a pin between her front teeth. The left temporo-maxillary joint was partially fixed; the right was more free. There was no facial deformity, no buccal scar, and no paralysis, but an occasional twitch of the left angle of the mouth. Sensibility was perfect; and she could forcibly contract both masseteric groups of muscles. She ate in a most inconvenient manner, being unable to masticate her food; she was compelled to push small morsels over the molar gums and then swallow them. There was no marked loss of flesh. No clear history of syphilis was given, but she has a small round tubercle by the parting of the frontal hair, and a diffused lump above the left olecranon. The diagnosis was fixity of the left temporo-maxillary joint by reason of condensed tissue around the pterygo-maxillary structures (left), and her twitch was explained by reflex action on the buccal branches of the fifth nerve. On Oct. 28th, 1878, having placed her under the influence of chloroform, by means of a screw and lever I failed to produce any increased motion of her lower jaw laterally or longitudinally. I therefore, on Nov. 6th, excised the left condyle of the lower jaw by an inch cut at right angles to the axis of its neck, nipped the neck across, and removed the condyle with the aid of a pointed lion forceps. Thus the inter-articular fibro-cartilage was left, and no injury done to the internal maxillary artery. There was trifling hæmorrhage; three of my fingers could be admitted simultaneously into the mouth, and she could protrude her tongue between her teeth on awakening. A small sponge was inserted into the wound; this was removed on the following day, and one silver stitch was applied as a compressing agent. She takes sop, and is much pleased at her regained power of eating with comfort. On Nov. 20th the wound had healed; she could speak plainly, and had masticated a quarter of a pound of mutton, after abstaining from solid flesh for eighteen months. On Dec. 8th she was busily assisting her fellow-patients to clear away the breakfast things, when suddenly blood flowed from her mouth and she dropped down dead. The post-mortem showed a large aortic and unsuspected aneurysm of the aorta, which had burst into the œsophagus. I have the skull and lower jaw on the table; and by the side of the lower jaw the condyle and neck removed by the operation I have described.

CASE 2.—Jane J——, aged nine, was admitted into Percy ward on Feb. 4th, 1879, for mechanical trismus, arising from asymmetrical development of the facial bones following scarlet fever. I removed the left condyle of her jaw on February 18th, with the immediate result of being able to open her mouth and insert my fingers. She continued to make good progress, the scar dwindling down to a slight straight line; and she was discharged from hospital on April 16th. She is growing up an interesting, though somewhat timid girl, with marked improvement in her power of speech and increasing facility of mastication.

CASE 3.—H. P——, aged forty-seven, clerk, was admitted into Mark Ward on May 9th, 1885, the subject of left trismus. About 1880 he suffered from toothache on the left side, and his teeth have never been very good. There was no history of syphilis. Fourteen months before admission his lower jaw became fixed; he could open his mouth wide enough to admit a silver fork, but no food on it. He applied for relief at Guy's Hospital and remained in for two months, but did not improve. He was recommended to come to Westminster Hospital by his employers. On admission his case was clearly one of unilateral trismus, and seemed to depend on some fixity below the zygoma and around the anterior aspect of the coronoid process of the lower jaw. Physical examination of the mouth was impossible. His breath was fetid, teeth numerous, and speech thick. He had lost flesh. As he had submitted to a most varied surgical discipline without any good result, I proposed excision of the condyle of the jaw on the left side. He readily consented, and as a preparatory measure I had his face shaved. Great was his surprise (for he had not been

shaven for sixteen years) to find immediately beneath his left malar bone a deep depressed cicatrix, of which previously he had no cognisance. On May 12th the operation was performed in the usual manner, and the condyle and part of the neck removed, also the attachment of the pterygoideus externus muscle. No difficulty was experienced, and there was no bleeding. The immediate result was that the mouth could be opened, and three fingers inserted. He was ordered as a gargle four drachms of chlorate of potash and three drachms of compound tincture of lavender, in a pint of water; and as a tonic, twenty minims of tincture of perchloride of iron, in water, three times a day. The man made an uninterrupted recovery, and left the hospital on May 30th, well able to eat and speak. The cicatrix is now being hidden by regrowth of his whiskers. On July 31st the patient was able to report good progress, the interval between the teeth being at the widest point three-quarters of an inch. On August 17th, 1886, I carefully examined him. When he opened his mouth there was found to be three-quarters of an inch between the incisors. He was free from annoyance. There was no fetor of breath, and no thickness of speech. The cicatrix was completely hidden by whiskers, and so also was the submalar one, about which we know nothing. He was able to eat half a pound of mutton for dinner, was gaining flesh, and had his old sense of well-being.

Why the operation has been performed.—A very few words will explain how miserable is the condition of a patient unable to eat or speak with comfort; how troublesome it is

Digitized by Google

to suffer from oral and dental fetor; how alarming to watch the gradual loss of flesh and healthful vivacity. Patients will direct the surgeon as to which of the two hinges of the jaw is at fault, and in all cases make a careful and minute examination of the facial skin and buccal mucous membrane. By the aid of this diagram (see engraving, *ante*) you will notice the line marking the spot for the excision of the condyle and neck of the jaw, and also the three succeeding lines showing the varying conditions of jaw leverage. In each instance, for the act of opening the jaw, let C be the fulcrum, P the power, and Q the weight. No. 1, the position of power and weight in any normal jaw. No. 2 (lever of the second order), the position of two fulcra in these conditions of unilateral trismus. No. 3, the position of power and weight, after the operation of removal of the condyle; or, in other language, the conversion of a normal mechanism of the jaw (lever of the second order) into that of an operated case (lever of the first order). Compare Nos. 1 and 3. And now look at No 2, which, in my opinion, explains the secret of many of these unilateral trismus cases, and also at this rough model I have cut out of wood, showing the condyle of the jaw, the mouth, and the temporo-malar coronoid structures. From dental irritation, or an old abscess, or other accident, a local definite adhesion results between the coronoid process and zygomatic fossa; or between or around the plane of the pterygo-maxillary ligament, fixing the lower to the upper jaw at any point between the teeth anteriorly and the temporo-maxillary joint posteriorly. It is obvious that any attempt to depress the symphysis is negatived by the new material (disease) acting as a fulcrum (instead of a movable mass); and as the condyle naturally is the fulcrum, there are two fulcra, and until one is knocked away (the condyle) no opening of the mouth can take place.

With what results this operation has been attended.—Professor Humphry's case (in 1855) of excision of the right condyle of the lower jaw for chronic rheumatic arthritis was successful; and in a letter sent to me in November, 1878, the Professor says: "The patient was well and able to masticate comfortably some years afterwards; the operation answered the purpose well." My three cases have also mechanically succeeded. Two are alive and well; the first died of syphilitic aneurysm of the aorta immediately after enjoying a good breakfast. I show you also to-day a specimen of chronic rheumatic arthritis of the temporo-maxillary joint (left side). This specimen came from our class subject in operative surgery (session 1884); for accidentally one of my pupils, in operating for the excision of the condyle of the inferior maxilla (an operation then taught by me as a recognised operation) came across genuine disease, and secured this not common preparation. We have on the table specimens of Case 1, superior and inferior maxillæ, condyle, and resultant cicatrix; Case 2, left condyle removed; Case 3, left condyle removed; operative specimen of arthritis of the temporo-maxillary joint. Strangely enough, all my preparations are left side specimens.

One word on the *method of operating*. Take the tragus of the ear as your guide, and make a horizontal incision (not more than an inch) across and down to the neck of the jaw, so as to allow cutting strong forceps to embrace the neck; divide the neck and evulse the condyle. This act of turning out the head of the bone may be done by the bone nippers or pointed strong bone forceps. I am tempted, while on this point of turning out heads of bone, to draw your attention to a valuable plan of impacting a strong steel lever into the cylindrical substance of the bone itself; this impaction not only gives a useful leverage in turning out small pieces of bone in cramped corners, but also allows the free play of the knife around and close to the bone, without the blades of any bone forceps coming in the way of sight or blunting the edge of the knife on the blades of the forceps. The leaving of the inter-articular fibro-cartilage prevents any future bony union occurring. Coupling, then, these three cases of my own with Professor Humphry's case, I am inclined to recommend the operation of excision of the condyle of the jaw for mechanical trismus. Instead of misery and inanition, by recourse to an easy and not dangerous operation the surgeon restores freedom of speech and reopens the gateway of alimentation; no large scar results, and in adult males this scar is hidden by hair. This operation affords another example of the warrantable sacrifice of perfectly healthy parts in one locality so as to effect the well-being and happiness of the whole body.

THE PATHOLOGY OF PUERPERAL ALBUMINURIA.[1]

BY ROBERT MAGUIRE, M.D. LOND., M.R.C.P.,
PHYSICIAN TO OUT-PATIENTS, AND JOINT LECTURER ON PATHOLOGY, ST. MARY'S HOSPITAL.

THE cases of puerperal albuminuria complicated with retinitis are of great importance, as presenting a feature which links the affection, in one of its forms, more closely to albuminuria the result of organic kidney mischief; and I should be glad if the ophthalmologists could tell us whether the occurrence of retinitis in puerperal cases has any influence on the prognosis of the albuminuria. The common form of puerperal albuminuria is characterised by the fact that in the later stages of pregnancy a large quantity of albumen appears in the urine, which, after delivery, disappears in a marvellously short space of time, and the patient then resumes her usual health. Such is a common course. But sometimes the termination is more serious: uræmia in its various forms may appear during the pregnancy and labour, or after delivery the albumen may still continue to appear in the urine, and the case may lapse into one of chronic Bright's disease. It is evident, then, that in the more serious form we have to do with an organic kidney lesion. This lesion was for long considered to be a venous hyperæmia from pressure; but, as a matter of fact, this has seldom been found, and, moreover, the urine of these cases is not in all respects the same as that met with in venous hyperæmia. A lesion more commonly found is the very opposite to this—that is, anæmia of the kidney with fatty degeneration, believed to be due to reflex spasm of the renal arteries, although obviously for this view there is no sufficient basis. But knowing that such a lesion is found, let us consider the more favourable cases, and inquire, how can it be that an extensive fatty degeneration of the kidney, and, what is more, a *chronic* fatty degeneration, should clear up in so short a time after delivery and leave no trace behind? *A priori*, this seems hardly possible. Such a consideration, too, brings into one's mind those cases of functional or cyclic albuminuria which are now occupying so largely the attention of physicians, and one cannot help asking whether also, in the less grave form of puerperal albuminuria we have to deal with a merely functional derangement. In this connexion I may be permitted to refer to some observations upon which I am engaged, and which, although not yet completed, have already yielded curious results. I will not go into details, for I purpose publishing the results later on in a more complete form.[2]

The precipitate obtained by the action of nitric acid or heat upon an albuminous urine is not one simple albuminous body, but is composed of serum-albumen—possibly in several varieties, only distinguishable by their *physical* properties,—and, in addition, a substance *chemically* different from serum-albumen—that is, globulin. This may be separated from the serum-albumen by saturating the neutralised urine with sulphate of magnesium in the cold; the globulin is precipitated in a soluble (non-coagulated) form, and the serum-albumen remains in solution. I am engaged in trying to determine what is the proportion of globulin to serum-albumen in albuminous urines, and whether this ratio varies in the different varieties of kidney disease, and in the different stages and phases of the same disease. Such a research seemed likely to throw light on the intimate pathology of albuminuria, and I specially hoped to find by this means a chemical diagnosis between albumen due to organic kidney disease, and that occurring, usually in cyclic rhythm, without kidney disease. My observations are as yet too limited in number to permit me any generalisation, but their results are certainly suggestive.

In four observations upon the urine of a case which presents all the most characteristic phenomena of functional albuminuria, I have found that the precipitate with nitric acid or heat is composed entirely of globulin, not a trace, or only the very faintest trace, of serum-albumen being present. This determination may be contrasted with that of a case of

[1] Being the basis of remarks made during a discussion on a case of Albuminuric Retinitis occurring in Pregnancy at the Harveian Society of London.

[2] See also THE LANCET, June 5th.

Digitized by Google

granular kidney, where, of the total amount of albumens, 70 per cent. was serum-albumen and 30 per cent. globulin; it may also be contrasted with that of a case of extreme general anæmia, and probably fatty degeneration of the kidney, in which, of the total amount of albumens, 30 per cent. was serum-albumen and 70 per cent. globulin. These figures are only approximations, but they will serve the present purpose equally well, with the decimals in which the determinations were worked out. In connexion with the latter case it may be mentioned that, if one may trust the clinical features, the disease was at first functional and afterwards became organic; and it will also be observed that, if the diagnosis be correct, there is here a kidney lesion, similar to that found, in one variety at least, of puerperal albuminuria.

Now, to come more directly to the point in discussion, I have examined the urine of one case of puerperal albuminuria in which the pregnancy and labour had terminated without mishap, and in which the urine, although still containing a large amount of albumen, was rapidly becoming normal. Here I found, as in the case of functional albuminuria already described, that there was an entire absence of serum-albumen and a precipitate with nitric acid and heat, which was composed entirely of globulin. Thus, if my observations be correct, and I of course admit that they must be multiplied before making any generalisation, this form, of puerperal albuminuria, which cures itself, is chemically allied to functional or cyclic albuminuria, and a strong suggestion arises that, as in the latter, so in the former, we have no organic kidney mischief. It is, from a practical point of view, highly desirable to diagnose during the progress of a pregnancy the one form associated with organic change, which will probably not recover, from the other form, in which, from what appears above, there is probably no organic change, and which will recover. Retinitis is a complication, which under other circumstances is generally found in connexion with organic change in the kidneys and serious symptoms. It is important, then, to ask if, when it occurs in puerperal albuminuria, it has the same grave significance; if the cases of puerperal albuminuria associated with retinitis invariably continue after delivery as cases of chronic Bright's disease; and if, finally, we may call this complication to our aid, possibly together with the chemical phenomena I have mentioned, in determining the prognosis of a given case. To summarise the above remarks, there is undoubtedly a form of puerperal albuminuria which is associated with an organic lesion of the kidney, and which we may call nephrogenic; but there is also another form, in which there is probably no such kidney lesion, which is probably due, as I believe, to the profound blood change of pregnancy, and which may hence be styled hæmatogenic.

Westbourne-terrace, W.

THE RATIONAL METHOD OF TREATING CATARACT PATIENTS, TO THE EXCLUSION OF COMPRESSES, BANDAGES, AND DARK ROOMS.

BY SIMEON SNELL,

OPHTHALMIC SURGEON TO THE SHEFFIELD GENERAL INFIRMARY AND TO THE INSTITUTION FOR THE BLIND; LECTURER ON OPHTHALMIC SURGERY AT THE SHEFFIELD SCHOOL OF MEDICINE.

THE title of this paper is similar to that of an article in the June number of the *American Journal of Ophthalmology* by Dr. Julian J. Chisolm, of Baltimore, and it is so expressive that I have adopted it.

The method proposed by Dr. Chisolm[1] is at variance with prevailing ideas, and marks, I believe, a revolution in our mode of treating cataract, and I would add many other cases. He asserts that all our efforts at extreme exclusion of light are both undesirable and unnecessary. The eyelid is the natural splint to the eye, and the globe covered with this allows about the same amount of light to pass into the eye as was the case before the cataract was extracted. He alludes, moreover, to the fact that while on the operating table, after removal of the opaque lens, and with a strong light on the face, there is no blinking or other evidence of suffering inconvenience from it. Further, he contends that the warm coverings over the eye and the great seclusion from light so often adopted are prime factors in the causation of the photophobia and lacrymation witnessed after cataract extraction, and in this way a means of prolonging convalescence. I have long felt this myself, and have therefore always been desirous of lessening the covering as speedily as possible. The method Dr. Chisolm advocates is to seal the eyelids with fine isinglass plaster in the manner to be mentioned presently. He records very excellent results in the sixteen cases of cataract extraction for which he had employed it; and he claims that there is less restriction for the patient with his method as to lying quiet on his back, the patient being allowed to sit up to his meals and to rise from bed when necessary, and that, as the eye is free from irritability, any covering is more quickly removed, convalescence is much more rapid, and the stay in hospital is shorter.

I am free to confess that I have seldom seen a paper that more directly appealed to me as to the justice and reasonableness of the conclusions set forth. The journal with the article in question reached me about the middle of July, and I immediately determined to adopt in practice the plan Chisolm advocated. I speak later on of the cases which have been so treated, but here I may say that the conclusion at which I have arrived from the results of those cases is such that I expect I shall be able to endorse Chisolm's words: "The revolution in the after-treatment of cataract and iridectomy patients in this hospital is complete. From this time hence, all bandages, compresses, and dark rooms will be among the things of the past, to be remembered only for the discomfort they occasioned." That is my present, and, I believe, will be my future, experience. The list of operations in which the method is applicable may, moreover, be extended, and it is useful in injuries of the conjunctiva, cornea, or sclerotic—in fact, in all wounds, operative or accidental, except those in which the discharge is likely to be free, and which would probably require a frequent change of plaster.

Passing to the operations in which I have employed it, I find a total of eighteen cases in hospital and private practice.[2] Twelve of these were operations on the crystalline lens, seven being extractions of senile cataracts, two traumatic cataracts, two removal of dislocated lenses, and one needling a soft cataract in a child. The extractions were as follow, and I take the first case as a typical one, and give it more in detail.

CASE 1.—Mrs. S——, aged sixty, a patient in the Sheffield General Infirmary, was operated upon on July 27th last. The cataract (left) was extracted by a shallow lower flap; a small iridectomy was performed, and there were no accidents attending the operation, which was done, as my practice is, in the ward, with the patient lying in her own bed. A 2 per cent. solution of cocaine, with salicylic acid, had previously been instilled. Both eyes were next sealed up with isinglass plaster in the manner to be presently referred to. The ward was not darkened, and a screen was placed round the bed more for the protection from currents of air than anything else. She made no complaint of the light. The next day everything was well; a very little secretion had exuded from the eyelids and become fixed in the plaster. She had been allowed more liberty as to moving about than is usually accorded to such patients. On the third day the eye looked well, and there was no complaint made. When the plaster was removed the patient immediately opened the eye, and bore light well; the wound had healed, and the eye was looking in every way satisfactory. The plaster was reapplied. On the fifth day the plaster was removed and a shade used over both eyes; the patient was allowed to get up. On the seventh day the patient was walking about the ward, and found no discomfort from the light. She was as well as most cases are between the second and third week. On the tenth day (August 6th) she left the infirmary, walking home unaided. In the other eye there was an incomplete cataract, and the sight was very indifferent.

CASE 2.—Male, aged sixty-one. Aug. 2nd: Extraction of old traumatic cataract.—6th: Shade used.—18th: Made out-patient.

CASE 3.—Female, aged seventy-three. Aug. 4th: Right

[1] Vide also THE LANCET, vol. ii. 1886, p. 296.

[2] Since the above was written, in ten additional cases my experience has been equally gratifying.

Digitized by Google

eye operated on. 6th: Plaster reapplied. 9th: Shade used. 18th: Left the infirmary.

CASE 4.—Male, aged sixty-six. August 9th: Right eye operated on. 12th: Plaster renewed. 14th: Shade used. On this day he was found up and eating his dinner with the shade pushed up.

CASE 5.—Male, aged sixty-three. August 16th: Right eye operated on.

CASE 6.—Male, aged forty-eight. August 16th: Right eye operated on.

CASE 7.—Male, aged sixty-three. August 16th: Left eye operated on.

In each of the above cases a shallow flap was formed; in some an iridectomy was performed, and in others not.

CASE 8.—Male, aged fifty-seven. July 23rd: Lens dislocated forwards; extraction below; shallow corneal flap. This case did well.

CASE 9.—Male, aged sixty-five. July 26th: Lens dislocated forwards. 29th: Shade used. August 9th: Made an out-patient.

The traumatic cataract cases were the following:—

CASE 10.—Male, aged twenty-six. July 19th: Cataract extracted through a small corneal wound. 21st: Shade allowed. 22nd: Made out-patient.

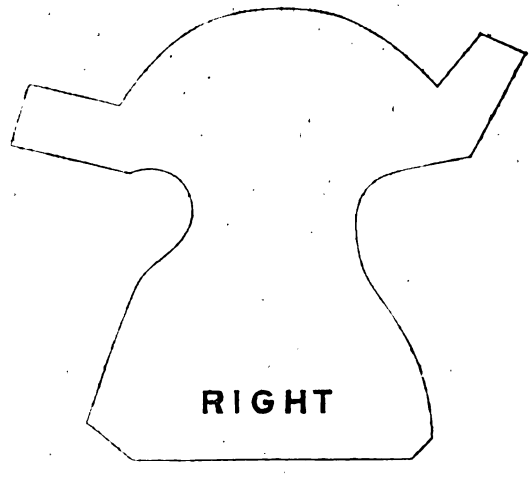
CASE 11.—Male, aged twenty. Aug. 2nd: Operation same as last. 4th: Shade used. 5th: Left the infirmary.

CASE 12.—A child. Lens needled on Aug. 16th.

CASES 13, 14, and 15.—Iridectomies; two being marginal ones in cases of zonular cataract.

CASE 16.—An iridectomy in a case after cataract extraction, with closed pupil.

CASE 17.—Needling opaque capsule after cataract operation.



CASE 18.—Sclerotomy in a man aged about forty.

Chisolm gives the following directions as to applying the plaster. "The lid of each eye was kept closed by a piece of isinglass plaster, 2½ in. long by 1½ in. wide. The piece of plaster, made thoroughly pliant by being soaked in water, was spread over the lids from brow to cheek, and carefully adjusted by stroking it with the rubber spoon used for pressing out the lens. In a very few minutes this piece of diaphonous silk plaster was dry, and the patient was ready to walk from the operating table to his bed in the fourth storey of the hospital." He elsewhere speaks of the piece of plaster being large enough to extend from cheek to brow and from one canthus to the other.

At first I adhered to these directions, but I was led soon to vary somewhat the plan. Thus I found it undesirable, and indeed unnecessary, to place the plaster over the eyebrow, and the next step was to cut the upper edge of the plaster to the curve of the orbital margin; and the advantage suggested itself of leaving a portion on either side to project at each orbital angle. The piece on the inner side was thus obliquely upwards, and the outer one was horizontal, for fixing it to the malar bone. Then, instead of reaching from canthus to canthus, it soon appeared advisable to constrict the plaster at the point where it passed over the margins of the lids and to leave a small space at either side for drainage, and the one on the inner side for the instillation of atropine or eserine drops. The shape of the plaster may be cut for each eye, but I have had a form made in metal which indicates probably the one generally required. Any particular alteration an eye needs is easily made. The annexed woodcut indicates the shape of the plaster, the silk side being uppermost. I have had the forms cut in the metal solid, as the drawing represents, and also as a hole in a plate of metal corresponding to the shape given. This latter is perhaps more useful, as it keeps the plaster flat at the time the shape is marked out on it.

The kind of plaster is of great moment. I have experimented with several kinds of silk, muslin, cambric, gauze, &c., and the form now used is the best yet arrived at, and, indeed, answers our purpose admirably. It is silk salicylated isinglass plaster (Seabury and Johnson's). It is quite transparent; put on a book it is very easy to read printing through it. It quickly dries, readily adheres, is easily fixed in its situation, and does not tend to curl up, which is often a characteristic of such plasters. The plaster, before being applied, may with advantage be a little snipped at several places along its edge to enable it to fit more accurately, and whilst it is drying it is often advantageous to push the cheek upwards to prevent displacement by facial muscular movements. In cataract cases it is essential to seal up both eyes, and this is generally true of other cases, but occasionally I have only closed one eye and often allow the sound organ liberty before the other is permitted it. It would appear that formerly in some hands plaster was used for closing the eyes after cataract operations, but I believe in a much less complete manner than Chisolm has advocated, and the routine practice, with perhaps every operator, has long been the use of bandages and pads, which his plan numbers among the things of the past. Such a method would hardly have been feasible in the pre-cocaine days. My experience of the plan is particularly gratifying, and is, moreover, pleasing alike to my assistant and the nurses.

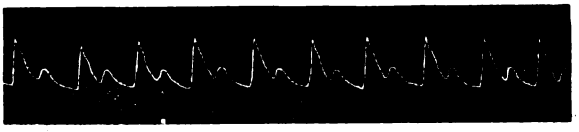
In conclusion, the advantages, particularly in cataract cases, of the plan Chisolm advocates over the routine method by bandages may be summed up under the following heads:—1. More comfortable to the patient, and less dread

of injury by movements. 2. Less discomfort to nurse and friends, or, in hospital, to other inmates of the ward, from less darkening of rooms. 3. Less liability to disturbance, and thus more freedom in movements permitted to patient. 4. More evenly and exactly fitting. 5. And thus allowing a more correct coaptation of wound, and, it is believed, experience will prove a more ready healing. 6. Inspection of eye is allowed without disturbance, for in this way swelling of lids or discharge are readily seen. 7. Affords a ready means of using eserine or atropine without disturbance of eye, and allows of drainage of tears, &c. 8. Absence of photophobia and lachrymation; when eye is opened, a ready examination in good light is allowed, patient being able to open eye fully. 9. Less confinement to bed, a quicker convalescence, and shorter stay in hospital.

Sheffield.

CLINICAL NOTES ON HÆMOPHILIA.

BY THOMAS OLIVER, M.D., M.R.C.P LOND.,
PHYSICIAN TO THE INFIRMARY, NEWCASTLE-UPON-TYNE; AND LECTURER ON PRACTICAL PHYSIOLOGY, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.



THE following cases of this interesting affection have lately come under my notice.

J. P——, aged thirty-three years, single, a groom, was admitted into the Newcastle Infirmary, complaining of bleeding from the mouth and of passing very dark-coloured urine. He told us that neither of his parents was a bleeder. An unmarried maternal uncle, however, used to bleed a great deal from the nose, and ultimately died after a vomiting of blood. A married sister of the patient has a tendency to bleed; and one of her sons, aged eight has frequently spontaneous hæmorrhages, which are with great difficulty controlled. The personal history of our patient is interesting. When but an infant in the cradle, a leech for some reason or other was applied to his side, and on that occasion, he has been told by his mother, the bleeding was with difficulty stopped. At the age of nine he was accidentally cut on the outer side of his right eye; this bled for several weeks. When he was fourteen he had a tooth extracted, and for a

Digitized by Google

week he had the cavity plugged; as this failed to check the hæmorrhage, a cork was fitted into the cavity, and the upper teeth were kept firmly clenched upon it for two or three weeks. Two years later he was cut between the right thumb and index finger, and for a month the bleeding continued more or less. At the age of nineteen he was wounded on the head, and for fourteen days he attended as an out-patient at the infirmary before the bleeding was stopped. About this time, too, he received a small wound, not much larger than a scratch, on the right arm, which bled for several days each time the dressings were changed. He has frequently had epistaxis, and it has always been with difficulty that the bleeding has been arrested. When he was twenty he passed blood in his urine, and again at the age of thirty; also at the beginning of the present attack. Each bleeding from the kidneys lasted for about a week. There was no bleeding during the first or second dentition. He states that a sharp tap on the skin is frequently followed by ecchymosis; that a strong blow causes a large swelling, particularly if the arms, calves, outer side, and back of thighs are made the seat of it. His joints, when moved sharply and suddenly, have frequently swelled and been painful, especially the knees and elbows. The swelling will last for a fortnight, and the veins over it are seen to be distended. Beyond having had small-pox and gonorrhœa within the last few years, there is nothing calling for notice until the beginning of the present attack. Three weeks before his admission the patient had been treated for pain in his right side. The medicine taken made his gums sore and swollen. On Sunday, May 24th, he awoke at 5 A.M. with his mouth full of blood. The blood oozed from his gums. That evening he had hæmaturia, which lasted until May 28th, and on this point I would remark that within three days of the disappearance of blood from the urine that fluid failed to exhibit the least trace of albumen. On May 26th the urine was port-wine-coloured, muddy, had a dark brown deposit, was faintly acid, sp. gr. 1018, contained a large quantity of albumen, and, microscopically, a large number of free blood-cells; pulse 80. In spite of rest in bed, and medicinal treatment by iron, ergot, hamamelis, &c., blood still oozed from the gums, though in diminished quantity. The gums remained swollen, pale, and ragged at their junction with the teeth. Beyond a slight rounding of the features and pallor of face, the patient presented nothing remarkable. His heart and lungs seemed healthy. On June 16th, feeling quite well, but with a tendency for blood still to ooze now and again from the gums, he left the hospital, only to be readmitted a few weeks later for a painful swelling of the knee-joints and bleeding from the gums. Fluctuation in the joints was well marked; movement of them was painful. When the swelling subsided, he left the hospital, cautioned as to the extreme necessity of taking care of himself. Six or seven weeks after this he was in a public-house with some friends. Two of the men began to quarrel, and just as words were about to be replaced by blows, our patient, while acting the part of mediator, was thrown violently against the side of the door. He went almost immediately to the infirmary, on entering through the porch of which he made some jocular remark as to the injury he had received. He was examined by one of the house-surgeons, who, unfortunately not knowing anything of his antecedents, did not detain him. To this official he complained of pain in the right side of the chest at the seventh rib, increased on forced inspiration, and slightly, too, on pressure. There was tenderness over the right pectoral region. His face was pale, but the lips were well coloured. Respiration was short and rather hurried; pulse 64. No fractured rib was detected. Expansion of chest appeared equal on both sides. The chest was carefully examined by those present: no dulness was detected either in front or behind; breath sounds were normal over the whole chest, save over each base posteriorly, where friction was heard, and also slight crepitus at the end of inspiration. As nothing else was observed, the case was regarded as one of bruise of the thoracic walls caused by a fall. A flannel bandage was applied firmly to the chest, and the patient was sent home, being told to lie in bed for a day or two. On the following day the man died unexpectedly. By order of the coroner a post-mortem examination was made about twenty-four hours afterwards by our house-physician, Mr. Waldy, to whom I am indebted for the report: "Rigor mortis not present; skin and mucous membranes very blanched; no external bruises or marks of any kind. On the right side of the chest, over the manubrium sterni and the three upper costal cartilages, was a distinct bulging, in which no fluctuation could be felt. Reflecting the skin, the great pectoral muscle on the right side was found distended with dark fluid blood. On cutting through the costal cartilages the same dark fluid blood flowed out of the chest. The anterior mediastinum was filled with the same material. From these sources a large basinful of fluid was removed. The right pleural cavity contained about two pints of similar dark-coloured fluid, and in addition several large clots about the size of the closed hand. The left pleural cavity contained a small quantity of dark fluid and blood clot. Both pleuræ were here and there adherent to the chest wall. No ruptured vessel could be detected, and no evidence of disease was found. It is possible that some pleural adhesion may have been torn."

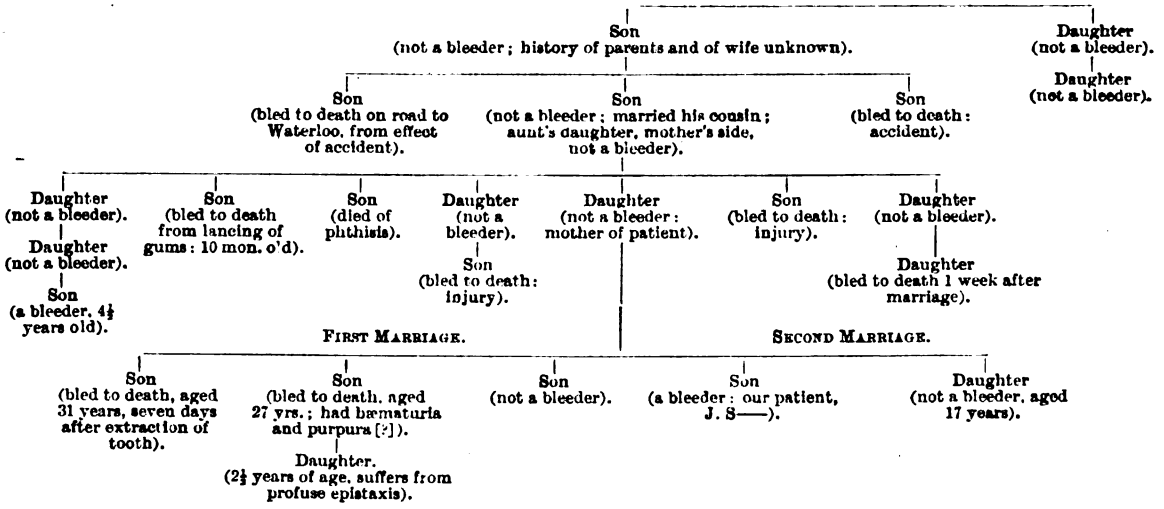
Scarcely had this patient passed out of sight than the following case was seen by me. J. S——, aged eighteen, an apprentice fitter in an iron foundry, a pale, sallow-looking lad, with rather a prominent brow and shape of head suggestive of previous hydrocephalus, went to the infirmary at midday complaining of toothache, and had the aching member extracted. It bled freely until 6 P.M., when he returned to the infirmary and was admitted. For forty-eight hours the bleeding continued, and that rather profusely. After that it ceased, but only temporarily, for every now and again hæmorrhage would start spontaneously from the socket. Strange, too, this bleeding generally came on at night. A few days after the extraction of the tooth the patient was so exhausted by the bleeding that he could scarcely stand. Five weeks after this he came to my out-patient department. He did not look even then as if he had recovered, nor for many weeks after. He told me that he never suffered from bleeding in his infancy. Ten years ago he was cut on the left thumb; this bled for a fortnight, and was followed by great exhaustion. With that exception he never had any severe bleeding until the extraction of the tooth. For six months prior to this, however, he had noticed that blood

in very small quantities oozed from his gums occasionally below the lower incisors. He has never spat or vomited blood, nor has he suffered from hæmaturia. The patient had two half-brothers, who bled to death; and he tells me that when they got a severe knock—and this applies also to himself—nothing would be noticed for a day or two, and then they would be laid up with "a swelling and colouring of the flesh." His joints have never swelled, nor have they been painful. So far as his chest is concerned, the respiratory murmur is healthy. The second sound of the heart is reduplicated over the apex and base, and the pulmonic is more accentuated, comparatively speaking, than the aortic. With these exceptions the sounds of the heart call for no remark. The pupils are dilated and respond to light. The pulse is 84, soft. A sphygmographic tracing shows low tension and large dicrotic wave, and bears a close resemblance to many tracings of ordinary anæmia. (See diagram.) When he had made a fair recovery he returned to work. He was only thus engaged a few weeks when he was struck on the right thigh by an iron wheel. The skin fortunately was not broken. The blow, though not severe, was followed by rapid swelling of the thigh, stiffness of the muscles, extreme pain on movement, and great discolouration of the skin. The effects of the injury were such that he was obliged to take to bed, and it was nearly a month before the swelling disappeared.

Hæmophilia is, as a rule, never detected until there is an injury. There is nothing which distinguishes the subjects of this affection from healthy people so far as outward appearances are concerned. It is true that in many a certain pallor of countenance, thinness of skin, light-blueness of eyes, and fairness of hair have been present; but these are far from being distinctive; besides the pallor is, in most of them, only noticed after a bleeding. In both of these cases the muscular system was well developed. One exhibited a marked tendency to swelling of the joints. Both suffered from ecchymosis and swelling of the skin after blows. I have not noticed in either of them a more diffused than normal impulse of the heart—a point to which Grandidier

Digitized by Google

drew attention. In one of the cases the second sound of the heart was strongly reduplicated; and the pulse, judged of by the sphygmographic tracing, shows low arterial tension. The spontaneous hæmorrhages generally came on at night—always from mucous membranes, save in the first case, in which there was occasionally hæmaturia. Only in the first case could it be said that there existed prodromata, and when present the hæmorrhage which followed was severe, and frequently from the kidney. The blood seemed in every instance simply to ooze out of the gums, and while no bleeding points could be seen, the actual amount of blood lost in a few hours was considerable. Whatever was done, the blood kept trickling, becoming paler the longer it flowed, and exhibiting less and less a tendency to clot. I do not know whether my first patient had taken blue pill or not. The medicine supplied to him before his admission into the infirmary caused his gums to be sore. Dr. Wickham Legg states in his monograph, on the authority of Burnes, that the taking of blue pill has been followed in these subjects by profuse hæmorrhage from the gums and nose, and that these symptoms recurred again and again when the blue pill was repeated. The patient himself attributed the bleeding from the gums on this occasion to the medicine he had taken.



On looking over the family history of the second case, it will be noticed that one of the members died of phthisis. The association of the two diseases here is slight, but as the occurrence of phthisis in the family of bleeders has been noticed before, the relationship is interesting as lending some support to the views of Dr. Reginald Thompson, who regards the excessive bleeding met with in many cases of phthisis as an expression of the hæmorrhagic diathesis. The relationship of hæmophilia to hæmatocele and other internal bleedings naturally comes to be considered. One of the females in the history of the second case died suddenly from some internal hæmorrhage about a week after her marriage. She was well two hours before death. As there was no external hæmorrhage, ruptured hymen could not have been the cause; and in the absence of post-mortem evidence such causes as bleeding from a ruptured ovary or ulceration of mucous membrane with or without perforation can at the best only be but conjectural.

The hæmorrhagic diathesis is more the inheritance of males than females. Both of the cases here reported are males. When women suffer, they appear to do so less intensely, although by some, it is said, that in them menstruation is profuse, and that at the climacteric period there is excess of hæmorrhage. Where these conditions are present, I should regard them as in all probability dependent upon a local cause. The sister of J. S—— menstruates normally, and is strong and healthy-looking; and as for his mother, she has, neither at her menstruation, parturition, nor at the climacteric period, lost more blood than the average. (See genealogical schema.) One cannot scan the schema of the family history of S—— without being struck by the remarkable influence of heredity in the development of hæmophilia, and by the striking manner in which the disease has skipped the females, only to appear in the most marked form in the sons, and to lead in them to a fatal issue on the slightest provocation. The potency of transmission by the female—she herself exhibiting no symptom of the affection—is shown in a remarkable manner in the mother of S——, who has been twice married. Two of three sons by her first marriage have died from the effects of bleeding, and of the son and daughter by the second marriage, the son has already been the subject of dangerous bleeding. The resemblance in this to the hereditary transmission of gout receives support from my case. So far as any connexion with scrofula is concerned, I see no indication unless the prominent forehead, the somewhat hydrocephalic shape of the skull generally, and the pallor and fineness of the skin of S—— may be taken as pointing in that direction. It is believed that hæmophilia is much more frequently met with in Germany than elsewhere, and as close intermarriage with relatives is there so little discouraged, it has been thought by Rieken that the marriage of cousins has something to do with its development. Two generations back, and in the lineal descent of J. S——, we meet with the marriage of first cousins; but while neither of these was a bleeder, it will be observed that two of the brothers on the male side died from hæmorrhage. The marriage of first cousins in this instance, however, had nothing whatever to do with the development of the disease.

In my first case the only prodromon noticed was pain in the back, and this always preceded hæmaturia. Most hæmophiliacs, however, suffer from a general sense of plethora for some time before a spontaneous bleeding occurs. They become in many instances too stout, and the face and lips become so highly coloured that it seems as if they must bleed. The mother of S—— tells me that in the case of the two sons whom she has lost plethora always preceded a spontaneous bleeding, and that in them the blood always came from the gums. When once bleeding has begun in these cases, not only is it difficult to check it, but when checked it is apt to come from other sources. In the case of the eldest son of Mrs. S——, whose death was due to hæmorrhage after the extraction of a tooth, no sooner was the bleeding stopped in the mouth than the most profuse epistaxis occurred, death supervening in his case on the seventh day. Profound exhaustion follows each bleeding. The urine in each of my cases, excluding the period of hæmaturia in P——, was normal. In the case of S—— the urine, examined several weeks after the last hæmorrhage, showed a diminution in the amount of urea eliminated daily. There was on an average only 218·5 grains eliminated daily—less than half the normal. A similar diminution was noticed by Grandidier, and is alluded to by Wickham Legg.

The second patient complained that his vision was imperfect. I sent him to Mr. Williamson, ophthalmic surgeon to our infirmary, for examination, who favoured me with the following report:—"Refraction myopic; both discs slightly swollen with large veins, crescent commencing at edge of each; choroid thinned from stretching; yellow spot seen in right eye with unusual distinctness. These

GENEALOGICAL SCHEMA (FAMILY OF S——).

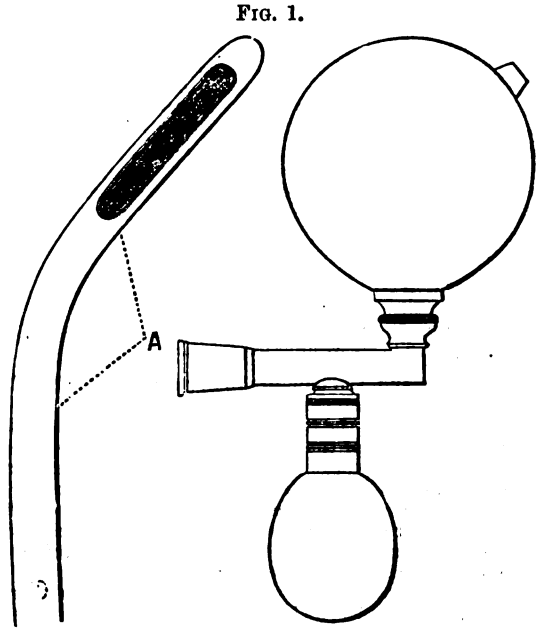
Digitized by Google

appearances are all accounted for by the gradual stretching and straining of a myopic eye."

I am inclined to regard cases of uncontrollable hæmorrhage from the cord in newly born children as instances of hæmophilia. It is true that in most of these cases one may fail to obtain a history of heredity; but is heredity, after all, absolutely required to constitute the disease? In most cases it is present, and forms a valuable point in the diagnosis, but whether really essential is another thing. Take the following case, which happened in the practice of a medical friend a few months ago:—A child is born at full time; it is plump, healthy-looking, and cries lustily. The cord is carefully tied and separated, and the child is given to the nurse. Before leaving the room the doctor has his attention drawn to the fact that the child is bleeding at the umbilicus. The cord is carefully examined, but exhibits nothing unusual. An additional ligature is placed around it and firmly secured. A few hours after this the nurse examines the child, and, finding its under-garments soaked with blood, the doctor is again sent for. Additional ligatures and hæmostatics are applied, but they are as nothing. The child dies from bleeding by the cord, unable to be checked. If the disease here is not hæmophilia, it must be something closely akin to it.

So far as the pathology of the disease is concerned, I believe the state of the blood and bloodvessels and a defective control-action on the part of the vaso-motor centres are the important factors in its causation. When the bleeding first commences there is a slight attempt at clotting, but it is never complete, and the longer the blood trickles the paler and more watery it becomes. To the plausible theory of Resal, that the subjects of hæmophilia possess an increased power of making blood, and that in them hæmorrhages occur amongst those capillaries which are thinnest, I cannot subscribe. My experience is that while plethora precedes the spontaneous hæmorrhages, hæmophiliacs recover extremely slowly from them. Such people feel exhausted for weeks it may be, and their pallor is long maintained. It seems to me that they have best health when pale. That a blood condition acts in some way or another as a cause we must admit, judging from the effects produced in other diseases where the blood is altered. In purpura and scurvy hæmorrhages are frequent; in some forms of anæmia and in certain diseases of the spleen a tendency to bleed is frequently noticed. I have known internal hæmorrhage in leukæmia prove fatal, and in a case of mitral stenosis and regurgitation in an anæmic young lady I have seen the incision of a gumboil followed by an alarmingly persistent hæmorrhage; the oozing lasting for days, in spite of plugging and strapping the jaws. In these cases of uncontrollable hæmorrhage, in which there is no hereditary history of bleeding, I am inclined to think that we have the thin-walled condition of the bloodvessels and the watery state of the blood met with in hæmophilia, and that it only requires the other factor, an inactive vaso-motor centre, to complete it.[1] In favour of the blood condition as a cause I would submit this, since I have noticed it again and again: Once the blood has undergone the marked alterations met with in leukæmia, it will be found that injuries which had been received years before the illness began bled but normally, and were easily restrained; but that slighter injuries received during the illness are followed by hæmorrhages slightly excessive and difficult to check. The healthy stimulus to the vaso-motor centre is healthy blood: alter the blood, and you either have its function increased, as in Bright's disease, or lowered, as, I believe, in hæmophilia. Everybody regards hæmophilia as most distinctly hereditary, and what does that mean? I take it to mean that during intra-uterine life the development of the cardio-vascular system is in some way or other interfered with, owing to the transmission of some ancestral peculiarity, the result of which is that not only is the blood itself altered and the tubes which carry it, but the nerve centres, which in later days regulate the distribution of the blood (states of dilatation and contraction of the arteries, the movements of the heart, and which must be therefore all closely associated together in their development), never reach a state of perfection. Complete control over the arteries and capillaries is therefore never the function of the vaso-motor centre in hæmophilia, and that this is the case is shown by the sphygmographic tracings. There is low arterial tension. Hence, when bleeding occurs the arteries do not contract sufficiently upon their contents owing to a want of proper impulses from the vaso-motor centre. I know not why the gums are the most usual seat of hæmorrhage in these cases unless it depend upon the rich vascular supply of their mucous membrane and the scanty support to the walls of the vessels—membranes, too, which are exposed to variations of atmospheric pressure and to all kinds of injury received during mastication.

Newcastle-on-Tyne.



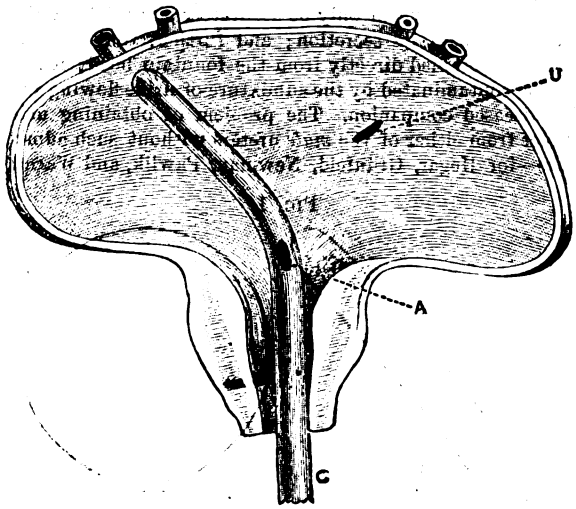
[1] On microscopical examination, I find the muscular fibres of the heart of P—— smaller than those of a man of his age, but healthy. The aorta was thinner than it should be, but on minute examination it is found to be quite healthy.

SUCTION OF THE MALE URETERS.

BY E. HURRY FENWICK, F.R.C.S.,
ASSISTANT-SURGEON TO THE LONDON HOSPITAL; SURGEON AND PATHOLOGIST TO ST. PETER'S HOSPITAL.

BEFORE we attempt to excise a kidney, it is obviously of the highest importance to ascertain the existence and the working capacity of its fellow gland. Upon the capacity of the latter to bear the double burden depends the advisability of the proposed nephrectomy. Now, the stress resistance of a kidney can only be accurately gauged by a rigid examination of its secretion; and further, that secretion must be obtained directly from the fountain head; it must not be contaminated by the admixture of urine flowing from its diseased companion. The problem of obtaining urine direct from either of the *male* ureters without such admixture—for Hegar, Grünfeld, Newman, Pawlik, and Warnots have shown how readily the *female* ureters may be isolated and catheterised—is as difficult as it is important. The labour expended upon the question is as yet unproductive, for the instruments, operations, and suggestions of Tuchmann, Silbermann, Ebermann, Weir, Sands, Glück, Harrison, and others are lacking—some in simplicity, some in safety, most in success. The instrument I would submit to the profession carries out, though perhaps indifferently, what I believe to be the only feasible method for engaging and tapping the male ureters. I have had it for two years, and have proved it to be simple, easy of application, but not infallible. The principle of its action is a slight suction force which is exerted upon the ureteral orifice by means of a catheter and a small indiarubber ball. This is, I believe, an exaggerated imitation of that aspiration which the normal bladder itself exerts upon the ureters.

FIG. 1.



Right-sided aspirating catheter with lateral eye; end piece, to which elastic ball and glass bottle are affixed. A, the measured angle.

It will be found that the normal bladder, unless it be in

Digitized by Google

cholera, never thoroughly contracts. Moreover, the smooth muscle wall sluggishly relaxes after its expulsive effort is over. This relaxation, at the same time that it produces a partial vacuum, diminishes the sphincteric contraction of the ureteral orifices, and any urine which may have collected in those passages is partially propelled by the *vis a tergo* of the circular muscle of the ureters and partially sucked by gravity and this negative pressure into the bladder. The aspirator consists of a small elastic ball and an oval glass bottle (see Fig. 1), which can be affixed to the end of a specially curved catheter, which latter is furnished with an elongated laterally placed eye. There are two catheters, one for each ureter. The bladder is first emptied and the catheter introduced. When it has fully entered, it is steadied and rotated over at the same time by the finger and the thumb, to the right or the left side according as the right or left ureter has to be engaged. The laterally placed eye will now be exactly over the ureteral orifice, for the angle A (Fig. 1) is the same as the normal angle which the outer side of the trigone builds with the long axis of the urethra. Fig. 2 shows the instrument in place. Pressure of the right hand upon the elastic ball empties it of its air, and its stem is then affixed to the end

FIG. 2.

C, Right-sided aspirator in position. U, Left ureteral orifice. A, Opening to receive urine from ureter.

of the catheter and the ball gradually released. The air in the catheter is correspondingly exhausted and the ureteral orifice is sucked into the eye, where it can be maintained by careful management of the ball, or by gentle counter-pressure of the finger in the rectum. In ten minutes sufficient urine will have collected in the catheter—for it rarely enters the glass bottle—to admit of an examination. I have lately had this catheter double channelled, so that the urine from the disengaged ureter may enter and drain off through the orifice A (Fig. 2) into a different receptacle.

I have said that it is not infallible. Sometimes there is but one ureteral orifice, as in a case I showed at the Pathological Society (1885-86). I found the ureters in another case (Path. Soc., 1886) much displaced by the action of circum-ureteral tubercular inflammation. Sometimes small bunches of villoid or other growth in the region of the ureters (three cases, Path. Soc., 1886) prevent close application of the eye and mislead by tinging the secretion with blood. A 20 per cent. solution of cocaine renders this slight operation painless. I have used the instrument in differential diagnosis of the site of symptomless hæmaturia, also in withdrawing scraps of growth from the trigone, and in performing an operation upon the kidney, the details of which I hope shortly to publish. The instrument can be obtained from Mayer and Meltzer, 71, Great Portland-street.

George-street, Hanover-square.

A CENTENARIAN.—On the 8th inst., at the meeting of the North Dublin guardians, Dr. Kenny, M.P., reported the death of an inmate of the workhouse at the age of 105 years. He was a sailor at the time of the Irish rebellion of 1798, and smoked tobacco up to the day of his death.

A NEW METHOD OF

REMOVAL OF THE ENTIRE TONGUE BY MEANS OF THE GALVANIC (OR SIMPLE WIRE) ECRASEUR AND SCISSORS.

BY FERDINAND ALBERT PURCELL, M.D., M.CH.,
SURGEON TO THE CANCER HOSPITAL.

IN my lecture given at the Cancer Hospital on Jan. 29th I demonstrated a new method for the removal of the entire tongue and floor of the mouth—applicable for removal of one-half of the organ if necessary—and presented a series of four cases operated on last year. I have christened it the "supra-hyo-glosso-epiglottidean method," which name anatomically describes the operation. The necessity for seeking for another mode for removal of part or the whole of the tongue is not that I have relinquished operating by the Whitehead or scissors method, combined with or without the preliminary tying of the linguals, or of performing first tracheotomy with the use of Trendelenburg's apparatus as used by Mr. Barker and Professor Kocher of Bern,—but that, in my experience, it may be in exceptional cases, in operating on the tongue, especially by the scissors or Whitehead method, bleeding has been the factor most difficult to combat, and its consequent result—namely, "surgical pneumonia." "Nothing is new under the sun," as the old saying goes; nor is it so in this, for Mr. Barwell so long ago as 1879[1] described his method, of which mine is the offspring; and recently I was much struck by a paper on a "Method of Controlling Bleeding during Complete or Partial Excision of Tongue" by Mr. Jordan Lloyd, of Queen's Hospital, Birmingham,[2] in which he applies steps of my method for the controlling of bleeding from the linguals.

With this factor the bleeding—it is of great importance that operations should be made easy for ordinary surgeons, and as bloodless as possible for patients whose powers have been weakened by pain, from deficient nutriment arising from difficulty of mastication and salivation, and anxiety, and who, after a severe operation, and having to submit to an absence of solid food, can be expected to bear well the loss of blood. My experience of my "supra-hyo-glosso-epiglottidean method" reduces our trouble from this source without any blood loss whatever, and by which is secured a very thorough removal of the tongue, together with the floor of the mouth and all structures down to the hyoid bone. I would recommend the surgeon, as Mr. Jordan Lloyd suggests, before attempting this procedure "to familiarise himself with the glosso-epiglottidean pouch, by palpation with an index finger introduced into its deepest part and another placed outside between the hyoid bone and the under surface of the angle and rami of the lower jaw; this anyone can try on himself; it is surprising how little tissue intervenes between the fingers, and how distinctly the various structures in relation to this space can be identified." It is necessary after removal of the tongue to have the cavity kept well drained by means of an indiarubber drain through the supra-hyoid opening, the parts dusted inside with iodoform, and the patient fed through an œsophageal tube.

The patient having been anæsthetised, first make an incision in the neck about a quarter of an inch long in the middle line from the hyoid bone forward, only skin deep; then pass a whipcord ligature through the raphé of the tongue an inch behind its tip, to hold the organ by; gag the mouth open; introduce the left index finger well to the bottom of the glosso-epiglottidean pouch, back of root of tongue. It may be necessary at this stage, so as to make room to get well round the base of the tongue, to snip with scissors the palato-glossi muscles—viz., the anterior pillars of the fauces, as also the stylo-glossi muscles of both sides; these may require pressure-forceps to be employed, as generally some small vessels may bleed; these can be taken off when wanted out of the way. Now take, say, Wood's hernia curved needle on handle, being stout, long, and well curved, threaded with medium-sized whipcord; or the needle in place of the thread may carry the platinum wire if the surgeon intends using the galvanic écraseur. Hold the needle in the right hand horizontally, its concavity turned

[1] THE LANCET, April 18th, 1879. [2] Ibid., Jan. 23rd, 1886.

Digitized by Google

upwards and towards the neck, enter its point at the submental incision immediately above the hyoid bone, pass it through the raphé of the mylo-hyoid, the genio-hyoid, and the lower fibres of the genio-hyo-glossi muscles, and direct it to the right side, forming the sweep of a half circle; now feel for the point of the needle with the left finger as the needle is pushed through so as to enter the bottom of the side of the right glosso-epiglottidean pouch above the great cornu, hook up the loop of thread, or it may be the platinum wire, with the left finger, pull it well through and out of the mouth, and withdraw the needle; do the same on the opposite side, for which it will be necessary to change the position of the hands, holding the needle in the left and placing the right index finger in the left side; a loop will in this way be lodged in the pouch at either side; thread each loop with the platinum wire, making a hook of wire by bending its end on itself; draw on both sides, so that the ends of the wire are brought out at the supra-hyoid incision, make even and detach the loops; the centre of the wire now forms a loop and rests on the base of the tongue. Before proceeding further, remove the pressure-forceps from off the cut anterior pillars of the fauces; take the same curved needle (Wood's), unarmed this time, and enter it again at the supra-hyoid incision in a vertical manner, its concavity directed towards you; feel for the point of the needle with the left finger as it is pushed through the centre of the root of the tongue and in front of the epiglottis; guard the point by means of a piece of cork, here the needle remains to act as a guide for the wire to travel behind; lodge the wire behind the guide and draw it taut, complete its connexions, and work the écraseur—the tongue is severed through its root in a well-defined vertical plane; withdraw the guide-needle. Secondly, free with scissors the anterior and lateral attachments of the tongue and floor of the mouth, release the organ and withdraw it through the lips. No hæmorrhage, as a rule, occurs; but if the battery or the écraseur should be worked too quickly and bleeding does take place, a sponge on a stick pressed into the furrow and following the wire will be found sufficient to restrain it; the linguals are included and cut through by the wire, and if they should so happen to spurt, they can be secured by pressure-forceps on the stump and tied. The ordinary simple écraseur, either single wire or twisted whipcord, may be substituted in place of the galvanic. The entire tongue may be removed as described, or the one half if so desired, by scoring the dorsum of the tongue with a blunt-pointed scalpel exactly in the middle line, and dividing the tip freely down and through the middle line of the frænum; then take both threads (one having been previously passed through each tip), one in each hand, and, using the forefingers much in the same way that one would for tightening a ligature on a deep vessel, split the tongue in two halves, and free the diseased half with scissors.

CASE 1. John M——, aged sixty-two, from Hampstead Union, was admitted into the Cancer Hospital, Ellis ward, on July 29th, 1885, under my care. Three years ago he first noticed a small ulcer at the base of the tongue, which was very painful. Has been a slight smoker. Has no history of phthisis or of syphilis. State on admission: Situate at the base of the tongue, and on the right of the median line, is an irregular excavated surface with indurated edges, its base covered with a slough. The whole extent of the ulcer cannot be fully determined; it extends as far back as the root. He cannot endure the finger to be inserted in his mouth. No enlarged glands are to be felt. He suffers great tenderness on the affected side; is unable to eat; dribbles saliva; feels weak, and is feeble and broken down; has an old ulcer on his leg. The patient was placed on the operating table on Aug. 1st. The hyo-glosso-epiglottidean operation by means of the galvanic écraseur and scissors, as described, was performed; the tongue was severed at its base, behind the anterior pillars, in a well-defined vertical plane. The action of the heated wire at first was too rapid, for it had not worked very long before some blood welled up. A stick sponge was pressed in the furrow following the wire, which restrained all bleeding; this was afterwards found to have come from a small superficial vessel immediately under the mucous membrane; the linguals gave no trouble. The mouth presented a deep excavated cavity; entire floor removed. A drainage-tube of good size was passed up through the opening in the neck, and the parts were dusted with iodoform. After twenty-four hours he was fed by means of the œsophageal tube. By the end of the month he was quite healed.

CASE 2. James W——, aged sixty-five, from St. George's Workhouse, was admitted into the Wolrige ward of the Cancer Hospital on Aug. 7th, 1885, under the care of Mr. F. B. Jessett. After operation he was attended by myself, my colleague having gone on his holiday. No history of cancer or of phthisis. Has had no serious illness. Became totally blind eleven years back. About nine months ago a pimple the size of a pea appeared on the left side of the tongue; this increased slowly. On admission there was on the left side of the tongue an ulcerated spot which could be covered with a two-shilling piece. Although it was irregular in outline, the edges of the ulcer were hard and the base uneven, being covered by unhealthy granulations. Situate beneath the extreme angle of the ramus of the right jaw a gland was enlarged, and another beneath the jaw on the left. On Aug. 11th the operation for entire removal of the tongue by the method described by means of the galvanic écraseur and scissors was performed. The gland on the left side was removed by an incision, and the wound sutured and sealed with styptic collodium. The gland of the right side was fished out of the floor of the mouth by the finger. The linguals spurted, but were seized in pressure-forceps and tied. Little blood was lost. A drainage-tube was passed up through the opening in the neck. The patient made a good recovery.

CASE 3.—Joseph R——, aged sixty, married (from Caerphilly, Cardiff), was admitted into the Cancer Hospital, Ellis ward, on Aug. 22nd, 1885, under my care. There was no history of phthisis or of syphilis. He never suffered from any serious illness. Has been a heavy smoker. His father had epethelioma of the lip; his mother died of old age. About nine weeks ago he first noticed that his tongue was being irritated by the teeth, two of which he had removed. The tongue, however, got worse, and rapidly ulcerated. The pain was severe, and he was greatly worried by continual dribbling of saliva. On admission, the tongue was fixed at the left side; ulceration, with induration extending back to the root, engaging anterior pillar and neighbouring soft palate; glands to be felt below mastoid process; emaciation; unable to masticate any food; was suffering great pain. On Aug. 29th I performed the hyo-glosso-epiglottidean operation, using the wire écraseur (instead of the galvanic) and scissors. The patient breathed badly under the anæsthetic. When about one-third through the tongue, the forcible constriction apparently closed the rima glottidis and caused asphyxia. The écraseur was not worked while artificial respiration was being performed. The patient looked bad, but had a capital pulse at the time. I proceeded to perform tracheotomy, and had made the incision, when the patient took in an inspiration, and a second, on which I desisted. I again worked the écraseur, pressing it upwards in place of pulling on the instrument; this being completed, the wire guide was removed, the anterior and lateral attachments were cut with scissors, and the tongue, released, was withdrawn. The lingual on the left side, having spurted, was seized and tied. The specimen was examined; it was found that the disease was not all removed. Using Paquelin's cautery, the parts were freely burnt, including the surface of the jaw-bone, as also the anterior pillar of the fauces and neighbouring soft palate; this worked away the structures to a much lower level on the diseased side, and by removing a piece somewhat larger than a walnut a clear view into the pharynx was obtained. A drainage-tube was then passed through the opening in the neck, and the parts dusted with iodoform. The patient made a good recovery.

CASE 4.—Joseph S——, aged forty-seven, married (from St. Paul's-road, Bristol), a sailor, was admitted into the Cancer Hospital on Aug. 25th, 1885, under my care. The right side of the tongue was ulcerated; induration and fixation of the organ on the same side; remains of a recent incision; glands enlarged on left side. No history of cancer or phthisis; always enjoyed good health; is a heavy smoker; usual stimulant is rum. About seven months ago he first noticed a small warty growth at the base of the tongue; this shortly afterwards disappeared. Then a lump came on the right side of the neck, the tongue became painful at the right side, and a white streak appeared. He was at the time on the coast of Africa, and was advised by his doctor to go home. He returned to Bristol and was admitted into the Bristol General Hospital, when the small growth was removed from the side of the tongue on April 2nd, 1885. After operation he suffered great pain, and on Aug. 11th the gustatory nerve was cut. State on admission: A strong healthy man.

Digitized by Google

Opposite the first molar tooth on the right side is a fissure extending as far as the median line; beneath surface ulcerated; organ bound down to floor of mouth; one or two glands enlarged below jaw. On Sept. 1st I performed this operation with the galvanic écraseur and scissors, severing the tongue close up to the epiglottis. One lingual spurted, and was tied. Where the tongue had been adherent on the right side, the parts were freely burnt with Paquelin's cautery, a drainage-tube passed up and the parts dusted with iodoform. He was fed during the night with nutrient enemata; next morning by means of the œsophageal tube. — Sept. 7th: Temperature 101°; some pneumonic râles; was delirious during the night.—22nd: Has passed through an attack of pneumonia; dulness still of the right side; inserted a hypodermic syringe needle into the right pleura, withdrew only a drop or two of pale fluid.—24th: Situate on the right side of the floor of the mouth there is a recurrent growth of the size of a hazel-nut.—Oct. 2nd: Had a copious discharge of purulent sputa; great fetor of breath; evidently an abscess of the lung has burst.—3rd: Had a rigor this morning; temperature 102·6°; right side of the chest fuller than the left. To inhale iodine vapour.

The patient eventually recovered. I had him again anæsthetised, and with Paquelin's cautery freely cauterised the floor of the mouth, destroying the recurrent growth. He afterwards made a good recovery, and left the hospital about Christmas. My patient replied to a query that appeared in *Tit Bits* as follows:—"Sir,—*Re* question 1926 of Nov. 21st, 1885, it may be interesting to your readers to know it is quite possible to talk without a tongue. The writer has not a particle of tongue remaining, as it was removed recently at this hospital on account of cancer. I may add I still retain a sense of taste and enjoy a capital appetite. I shall be pleased to answer any further questions on this matter, and if you think fit to publish this you are quite at liberty.—Yours, &c., Captain S——, Wolrige ward, Cancer Hospital, S.W."

PARALYSIS DEPENDING UPON IDEA.

BY C. W. SUCKLING, M.D. LOND., M.R.C.P.,
PHYSICIAN TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

IN the *Birmingham Medical Review* for June, 1885, I published an account of a boy who had suffered from paralysis of one leg for two years, and whom I was able to cure immediately after making the diagnosis of paralysis depending upon idea. Since then I have met with three other cases, two of which were men. In one case there was complete anæsthesia of the hand; in another hemi-analgesia with localised and severe headache. In the four cases I have now seen, an accident occasioning slight injury was the exciting cause in each. All four cases were rapidly cured. Dr. Russell Reynolds, I believe, first described paralysis depending upon imagination. There is no malingering in these cases, but the patients are firmly convinced that they are suffering from paralysis. If the confidence of the patient be gained, an immediate recovery follows when he is told that he will be well immediately, the idea being got rid of. In making the diagnosis it is important to bear in mind the two classes of people in whom functional nervous disorders are met with—the neurotic and the hysterical; the features of which have been so graphically described by Dr. Clifford Allbutt in the Gulstonian Lectures for 1884. It is the neurotic that is apt to be affected by these paralyses depending upon idea, and it is these cases that are instantly cured when the diagnosis is made. The hysterical patient is cured with difficulty and frequently relapses; the neurotic does not relapse. The neurotic individual is vivacious, good-tempered, unselfish, intelligent, active and industrious, anxious to be cured, and grateful for recovery. The hysterical individual is listless, apathetic, lazy, selfish, with characteristic expression, not usually anxious to get well or thankful for recovery. The following is the fourth of these cases of paralysis depending upon idea that I have met with during the last twelve months.

Sarah F——, a widow, aged forty-six, was sent to the Queen's Hospital, to be admitted under my care, by Dr. Middleton, of Harborne, on the 15th of March last, and was discharged well on March 28th. She has led a very industrious life, having supported her five children by needlework since her husband's death ten years ago. On Oct. 9th, 1885, she tumbled downstairs, falling down twenty-one steps on to her back. She was much hurt and "dazed" and very much frightened, thinking every bone in her body was broken. She walked about after the accident for a day or two, but suffered from pains in the back, down the legs, and round the body; these pains were intermittent, very severe, and lasted altogether three weeks. Two days after the accident she took to her bed, and a day or two later found that she was paralysed in both her legs and had lost all feeling in them. Since the accident she had suffered from constant headache and backache. Upon examining her I found that she had a little power over the legs, but very little. Slight ankle-clonus could be elicited on the left side. The plantar and abdominal reflexes were lost, but the knee-jerk was well-marked. There was complete analgesia and thermal anæsthesia in both legs up to the knees. She was unable to localise tactile sensations below the knees, the anæsthesia not being complete. When touched with a sharp-pointed instrument she said she felt as if she were being pushed. Muscular sense was unaffected. There was superficial tenderness over the lower dorsal spines, but no pain on firm pressure or on percussion, and no irregularity of the spine. The bladder and rectum were unaffected, and I was informed by Dr. Middleton that she never lost control over the bladder, nor had any sign of bedsore during her illness. There was no œdema of the legs, no alteration of temperature, and no change in the colour or aspect of the skin or nails. In fact, there were absolutely no trophic changes whatever. The response of the muscles to faradisation of their nerves was normal, but there was considerable electrical anæsthesia. In summing up the symptoms present, I of course observed their incongruity if we supposed the case to be one of myelitis, or, in fact, as due to any organic lesion. If the anæsthesia were due to actual lesion of the grey matter, how could the bladder and rectum escape? How was it that there was no sign of bedsore, no œdema, or other trophic change, such as muscular wasting? I diagnosed the case immediately as being purely functional, and, the woman being of the neurotic type, as paraplegia depending upon idea. I at once acted upon this diagnosis, and told the patient that I should give her the battery, which I said would at once remove the loss of sensation and enable her to move her legs as well as she ever did. She was delighted to hear this, and after a minute's faradisation sensation was completely restored, and she had full command over her legs. I then told her that on my next visit I should expect to see her walking about the ward, for I was sure that she would be able to do so. I instructed Mr. Whittendale, my house-physician, to see that she got up after I left, and to apply the faradaic current whenever she displayed any hesitancy. On my next visit, two days later, I found her up and able to walk and run about the ward perfectly well. She was quite delighted at her recovery, and had been most industrious with her needle since getting up. She expressed deep gratitude, and hoped to be able to repay our kindness. I may add that I saw my patient on the 14th of the present month (September), and she was remaining quite well.

How was the cure effected in this case? Undoubtedly, I think, it was by the mental state of faith or expectation, or both, on the patient's part. She fully believed what I told her, and thus I was able to remove the idea she had that she was paralysed. The essential thing, then, in these cases is to make a correct diagnosis, and then the patients can safely and with success be told that they will quickly recover. Now, had this been a hysterical woman, I should in all probability have failed to cure her, or, at any rate, the cure would have been more tedious. I recently had a woman under my care suffering from locomotor ataxy with hysterical anæsthesia. For two years I did all I could to cure the anæsthesia, and failed; but when she left the infirmary she applied leeches to her legs and returned with the anæsthesia gone. Isolation, so useful in hysterical cases, is not needed in these.

In the same ward with my case of ideal paralysis there was a young woman suffering from hysterical neuralgia, and the contrast between the two patients was very marked. The hysterical woman was listless and apathetic, did not manifest any desire to be cured, and would scarcely allow that she was any better than when admitted. When told that she was well enough to go back to her duties as a

Digitized by Google

teacher, she seemed disappointed, and said that she did not intend to begin work again for some months. The neurotic woman, on the contrary, wanted to leave the hospital immediately she could walk. The hysterical woman was observed to be always sitting opposite the neurotic woman, contemplating her with her hands idly folded in her lap, watching the other busily working.

Such cases as these illustrate the enormous influence of the mind over the body. It is with these cases that the so-called faith-healers work pretended miracles. What an opportunity for a faith-healer my case would have afforded! Just as the mind has an enormous influence in causing disorders of sensation, of motion, and also of the organic functions, so also its influence can be used as a practical remedy in disease. As Dr. Wilks has well observed, "the practice of medicine is not only one of physic, but of psychology also."

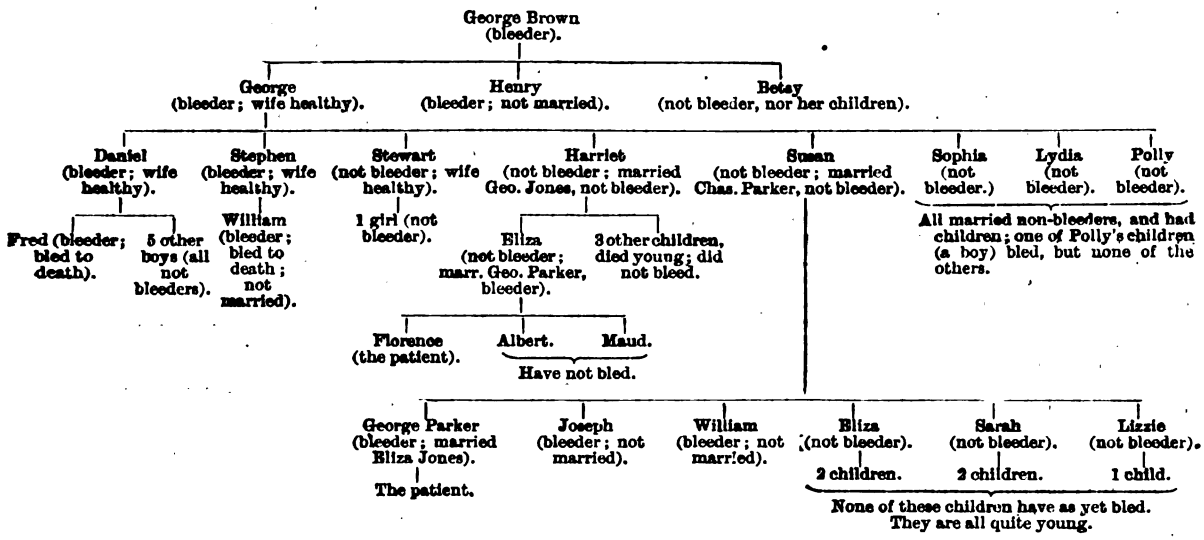
LONDON HOSPITAL.

A CASE OF HÆMOPHILIA; PEDIGREE THROUGH FIVE GENERATIONS.

(Under the care of Mr. FREDERICK TREVES.)



THIS case of hæmophilia is interesting, as Mr. Treves remarks, from the sex, and from the clear account of the pedigree of the patient which is appended, and which shows so well the transmission of the disease from parent to children. It is seldom that the most assiduous search can trace the family history of any case so far back, especially when the patient comes from the rank of life to which this girl belongs.

Florence P——, aged six, was admitted on January 26th, 1886, under the care of Mr. Treves, for obstinate bleeding from the mouth. On Jan. 24th the right second molar of the lower jaw had been extracted. Within an hour and a half after the operation the socket began to bleed; there was little or no bleeding at the time of the extraction. The socket was plugged and the hæmorrhage was checked for some twelve hours. It recurred, but ceased after a second plugging. There was no bleeding for the next twenty-four hours. It then reappeared, and all means adopted to check it failed. The hæmorrhage had been considerable; large clots of blood had formed in the mouth and had been removed from time to time. On admission the patient was perfectly blanched and in a dangerously exhausted condition, a little watery blood still oozing from the mouth. The child was well developed and of fair complexion, the eyes being blue and the hair very light; the skin was singularly smooth and delicate; the teeth were well formed. The child had always enjoyed good health. No enlarged glands had been felt in any part. The extremities had been always of normal temperature. The patient did not complain unduly of cold, and had never had chilblains. She had never bled before, nor had unusual ecchymoses followed casual contusions. She was not an excitable child, and appeared to be in perfect health when the bleeding commenced. The tooth was extracted entire and without difficulty. The father and mother were first cousins. They were natives of Essex, and in that county the family had resided for many generations. Both parents enjoyed good health. The father had suffered from three attacks of bleeding, and each time had nearly lost his life. On the first occasion there had been a cut on the thumb, on the second a cut of the index finger, and on the third a tooth had been extracted. The parents were members of a well-known "bleeder" family. There were two other children besides the present patient. They were infants, and had never bled.

The socket of the tooth was very carefully plugged with ferrated cotton-wool. Ergotine and gallic acid were administered. The child bled slightly on three occasions between Jan. 26th and Jan. 31st, the hæmorrhage each time being arrested by plugging with ferrated cotton-wool. The child left the hospital on Feb. 8th, no blood having been lost for eight days, and no plug having been used for that length of time. She was still very weak and anæmic, and was taking a preparation of iron.

Remarks by Mr. TREVES.—Three cases of hæmophilia have come under my care in the hospital during twelve months. The present example is the most noteworthy, inasmuch as the patient was a female, and a very complete history of her family was provided by her mother and grandmother. The researches of Grandidier, Wachsmuth, Wickham Legg, and others have served to display the remarkable heredity of this disease and the still more remarkable manner in which it is transmitted. It is known that the affection cumulates in certain families—the so-called bleeder families; and statistics show that there are nearly three bleeders to every family affected. The disease, moreover, is thirteen times more common in males than in females. It has been clearly proved that it is transmitted not so much by the bleeders themselves as by their non-bleeder brothers and sisters. The extraordinary fruitfulness of the latter has often been marked. Wachsmuth states that the average number of legitimate births in bleeder circles is nearly double the ordinary average. In the transmission of the disease the preponderance of the maternal

PEDIGREE OF THE FAMILY OF FLORENCE P——.

Digitized by Google

influence is very conspicuous. It may be almost said that the females hand down the disease, while the males are the victims of it. Grandidier has formulated the following points in this connexion:—1. Males in bleeder families who are themselves bleeders do not as a rule beget bleeder children by women who belong to non-bleeder families; in fact, the children in this case are usually healthy. On the other hand, the children of women who are themselves bleeders are quite uniformly subjects of hæmophilia. 2. Males in bleeder families who are not bleeders almost never beget bleeder children by women from other families. On the other hand, among the children of women who belong to bleeder families without being themselves bleeders, there are almost always some who suffer from hæmophilia. The family history of the present patient affords an interesting comment upon these statements. (In the Table the actual Christian names have been preserved, while the surnames are fictitious.) It will be seen how the females of the family were free from the disease, while nearly all the males were subjects of it. So far as the pedigree extends no female had hæmophilia until two first cousins married. The present patient was their eldest child. It will be seen also that in several instances male bleeders who married healthy wives had children who were the subjects of this disease; while, on the other hand, by no means all the children of the females of the bleeder family exhibited the phenomena of hæmophilia. (See pedigree.)

ST. MARY'S HOSPITAL, MANCHESTER.

CASE OF ALBUMINURIA DURING PREGNANCY; INDUCTION OF PREMATURE LABOUR; RECOVERY.

(Under the care of Dr. C. J. CULLINGWORTH.)

For the notes of the following case we are indebted to Dr. Archibald Donald, house-surgeon and resident assistant obstetric surgeon.

E. M——, aged twenty-six, a cheerful, intelligent, well-nourished young woman, pregnant for the first time, was admitted into the hospital, March 5th, 1886, suffering from extensive anasarca. She had been married about ten months, and had last menstruated on Aug. 20th, 1885. The fundus uteri reached to an inch above the umbilicus; the fœtal heart sounds and uterine souffle were both audible. The first symptoms of swelling were noticed in the feet six weeks previous to her admission. Within a few days from that time the swelling had become very marked over the whole body, the face, hands, trunk, and legs being all implicated. It was not until a few days before her admission that she observed the urine to be scanty and high-coloured. She had not felt fœtal movements, and was, in fact, not aware that she was pregnant. Her health before this illness had been uninterruptedly good.

On admission, there was very considerable œdema of the whole surface of the body; the eyelids were greatly swollen, as well as the trunk, and all the extremities. There was also evidence of a considerable amount of ascites. The urine was brownish-red in colour, acid in reaction, of sp. gr. 1020, and became almost solid on the addition of nitric acid. In the sediment were found blood-corpuscles, tube-casts (hyaline and blood), and renal epithelium. A consultation was held, and it was decided, before adopting means to cut short the pregnancy, to try the effect of rest in bed and medicinal treatment. Accordingly, hydragogue cathartics were administered, and hot-air baths. Subsequently nitrate of pilocarpine, in doses of one-third of a grain, was injected subcutaneously once a day for three days. As this had no effect whatever, the liquid extract of jaborandi was given by the mouth, with an equally disappointing result. Indeed, of all the means that were tried, dry cupping over the loins and over the bases of the lungs, was the only one that was followed by even temporary benefit. The anasarca meanwhile increased, and œdema of the lungs set in, with great dyspnœa, and a most harassing and constant cough. The patient was unable to lie down night or day, and became so weak that the urine was from time to time expelled involuntarily. The skin was very dry. The temperature did not rise much above 100°.

On March 16th (eleven days after admission), matters had become so urgent that Dr. Cullingworth gave directions for premature labour to be induced without further delay. Accordingly, at 9.30 P.M., a gum-elastic bougie was passed to the extent of about six inches into the uterus. Pains commenced at 2 A.M. on the 17th; at 6 A.M. they had become severe; at 7 A.M. there was an attack of hæmorrhage, one or two large clots accompanying it; a few minutes later the membranes were ruptured spontaneously (the os uteri being nearly fully dilated); and at 7.40 A.M. a living fœtus of apparently between six and seven months was expelled naturally. The placenta not having come away in due time, expression was tried, but without success. The hand was accordingly introduced, and it was then found that the placenta was partially adherent to the posterior wall of the uterus, just above the internal os. After detaching and removing the placenta, the uterus was injected with hot carbolised water. The amount of hæmorrhage during the third stage of labour was considerable. In the evening the dyspnœa and cough were very troublesome, and the patient was very restless. This condition lasted for several days. During the two days following confinement 160 oz. of urine were drawn off. (The average daily quantity a few days before labour was 25 oz.) The anasarca now became speedily diminished. On March 23rd, the patient's general condition was much improved, the dyspnœa having quite disappeared and the cough being much better. The amount of albumen in the urine was now reduced to one-sixth; the daily quantity of urine was about 68 oz., and the specific gravity about 1010. The colour was light yellow; no casts were discoverable. From this time convalescence was established very rapidly. On April 10th the last trace of albumen had disappeared from the urine, and on the 17th the patient was discharged well. The child only survived its birth about thirty hours.

Remarks by Dr. CULLINGWORTH.—There are several points of interest in this case. 1. It affords a striking illustration of the fact, already well known, that very pronounced albuminuria may exist during pregnancy without eclampsia. The urine here was loaded with albumen, and the œdema was intense; yet not only were there no convulsions before labour, but (what is more important) none were excited by the manipulations necessary for inducing premature labour. How far we have to thank the exceptionally cheerful and placid disposition of the patient for this immunity I cannot say. It is quite possible that the absence of anything like extreme previous irritability was the one fortunate circumstance that saved the patient from convulsions. 2. It is to be noted how completely all palliative measures failed so long as the pregnancy continued. I was particularly struck with the utter uselessness of pilocarpine in this case. The beneficial results obtained from its administration in puerperal eclampsia by Horrocks[1] and Murphy[2] naturally encouraged the hope that equally satisfactory effects would follow its use in uncomplicated cases of the acute albuminuria of pregnancy. The case here recorded seemed to afford an excellent opportunity for teaching how far such a hope is likely to be realised. Three injections of a freshly-made solution, obtained specially for the purpose, were administered in doses of one-third of a grain at intervals of about twenty-four hours. No appreciable effect followed. The result seems also to show that further evidence is necessary before Dr. Horrocks's statement as to the ecbolic action of pilocarpine can be accepted. 3. The prompt recovery of the patient as soon as the uterus was relieved of its contents (notwithstanding the loss of blood occasioned by the faulty position and adhesion of the placenta) points to the induction of premature labour as the proper and hopeful treatment in severe cases, where other and less radical measures have been fairly tried and found useless.

LIVERPOOL HOSPITAL SUNDAY FUND.—At the meeting of the committee of this fund held last week it was reported that the total amount for disposal was £9250, as against £8880 last year. It was unanimously resolved to hold over for further consideration a grant to the Hospital for Women in Shaw-street, but amongst the awards granted were the following:—Royal Infirmary, £2312 10s.; Royal Southern Hospital, £1387 10s.; Northern Hospital, £1202 10s.; The Dispensaries, £647 10s.; Infirmary for Children, £555; Stanley Hospital, £462 10s.; Eye and Ear Infirmary, £462 10s.; Hospital for Consumption, £277 10s.; St. Paul's Eye and Ear Hospital, £138 15s.; Hospital for Cancer and Skin Diseases, £92 10s.; Netherfield Institution for Infectious Diseases, £92 10s.; Dental Hospital, £23 2s. 6d.; St. George's Hospital for Skin Diseases, £23 2s. 6d.

Reviews and Notices of Books.

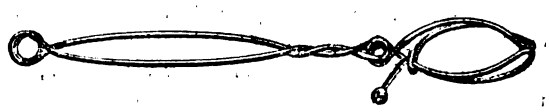
On Cancer of the Mouth, Tongue, and Alimentary Tract: their Pathology, Symptoms, Diagnosis, and Treatment. By FREDERICK BOWREMAN JESSETT, F.R.C.S., Surgeon to the Cancer Hospital, Brompton. With numerous illustrations. London: J. and A. Churchill. 1886.

THE aim of this book has been to discuss our present knowledge and views of the treatment of cancer of the mouth, tongue, and alimentary canal. The author states that he knows "of no separate work or monograph which treats specially on this very important subject"; and he adduces this fact as the ground of his choice of a subject for his monograph. To many people it will appear to be a strong reason why such a book was not particularly called for. We can well conceive the value of a treatise on cancer in general in which the peculiar pathological and clinical features of this dread disease are discussed. We can also appreciate the advantage of monographs devoted to the affections of particular organs. But we know of no reason why a book should be devoted to the consideration of one particular disease as it affects such a series of organs as Mr. Jessett has chosen, especially when no attempt is made to show any leading pathological or clinical features common to the whole. But, after all, the book is before us, and we are more concerned with what Mr. Jessett has written than why he has written it. Some of the most important surgical diseases are embraced in the author's group, and any careful discussion of the diagnosis and treatment of cancer of the tongue and rectum or of the best modes of dealing with malignant stricture of the pylorus and œsophagus must be of interest to surgeons. We find a table of over fifty cases of cancer of the tongue submitted to operation, and another of sixty cases of gastrostomy for cancer of the œsophagus, which have been collected from various sources. These are good features of the book, as are the statistics culled from the note-books of the Cancer Hospital. But having said this, we are afraid we cannot add that Mr. Jessett has added materially to our knowledge of the diseases about which he has written. He leaves us a little uncertain as to his opinion on the much-discussed question of the local or constitutional nature of cancer. Thus on page 86 we read in respect to cancer of the tongue: "I, however, regard the disease as a local affection, so far as it does not, or very rarely, attack any other organ in the body; and I therefore consider, if the disease is removed early enough and thoroughly, there is little chance of its returning in the site of the cicatrix." And on page 90 we read: "I believe it to be a constitutional (I use the word in its widest sense) and not a purely local disease."

Some novel and important views in reference to tubercular ulceration of the tongue are advanced, first as to the mode of origin of this disease, and then as to its relation to epithelioma. Mr. Jessett states that a tubercular ulcer on the tongue is always secondary to deposits of tubercle in the lungs, and in this he is in accord with other observers. But he goes on to suggest that "the ulcer is originally a simple one, and becomes tubercular by being inoculated by the bacilli in the sputum which is continually being ejected from the lungs." And on the very same page we read: "The ulcer commences in the submucous tissue, usually as a smooth, hard nodule"—a statement directly opposed to the former view, and indicating that the ulcer is formed by the disintegration of a tubercular nodule.

Of more consequence is the assertion that "tubercular ulcers are very liable to take on a malignant character." This opinion is strongly expressed (p. 70), and upon it is founded the advice to excise obstinate tubercular ulcers. "I would therefore, in cases of tubercular ulcer, unless it speedily heals under treatment, strongly recommend its early removal." Mr. Jessett does not offer any evidence in support of this view, and he does not give his readers the facts which have led him to form his strong opinion. In the absence of such evidence he has taken upon himself a very grave responsibility in urging the excision of tubercular ulcers. Indeed, the reasonableness of this advice is hard to perceive, especially from the author's standpoint. For he insists, first of all, that such patients are always the subjects of pulmonary tubercle, and that the ulcers on the tongue begin as simple ulcers and are then infected. If so, the excision of a tubercular ulcer must leave behind a simple ulcer which is constantly exposed to infection from tubercular sputa. On all grounds, therefore, we hold that such a statement as this should not have been made without distinct and even strong evidence to support it.

Among the means of relieving the pain in cancer of the tongue, division of the gustatory nerve is of course mentioned, but we are surprised that Mr. Jessett does not refer to the ease with which the nerve can be found where it lies along the under side of the tongue; one great advantage that operation upon the nerve here has over Hilton's and Moore's methods is the fact that a considerable length of the nerve can be excised.



How to Foretell the Weather with the Pocket Spectroscope. By F. W. CORY, M.R.C.S., F.R. Met. Soc., &c. London: Chatto and Windus.

METEOROLOGICAL SCIENCE, which until a few years back had but few votaries, has recently given signs of vigorous life, and the daily weather forecasts are now probably as diligently scanned as the quotations of the money market. There is more satisfaction, however, in making weather observations for oneself, and Mr. Cory, in the *brochure* under notice, describes lucidly and minutely how such observations may be made with the hygro-spectroscope, an instrument the use of which, the author believes, will mark the commencement of "a fresh branch of meteorology that will eventually supply the missing link in forecasting, annihilate its difficulties, and bring to our knowledge facts about the upper regions of the atmosphere that were never dreamt of in our philosophy." The spectroscope, however, it must be stated, is not extolled as an infallible indicator of the kind of weather in the near future, but only as a valuable adjunct to other means of forecasting. In the rush of modern daily life, when arrangements for business or pleasure have to be made to fit in with seasons of routine work, the advantage of being able to anticipate with some degree of certainty the sort of weather approaching cannot be doubted, and this power the little work of Mr. Cory's will go far to put within the reach of those who will take the trouble to master its contents.

New Inventions.

NEW SPONGE-HOLDER AND DRESSING FORCEPS.

THIS simple instrument (which has been designed by Dr. J. Ward Cousins) will be found very useful in many surgical operations. It is made of twisted wire, and the grip of the blades is sufficient for holding securely sponges

of various sizes and pledgets of cotton-wool. By pressing the thumb on the spring the points are relaxed, so that the material can be charged with great facility. It is manufactured in several sizes by Messrs. Maw, Son, and Thompson.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 18, 1886.

Two gentlemen are specially entitled to the thanks of the country for their speeches on the motion of Mr. ARTHUR O'CONNOR for withholding £16,500 of the grant of £445,956 for the Local Government Board. The £16,500 is the sum given to vaccination officers. In the estimation of this gentleman it is the mainstay of an immoral, stupid, and cruel system, inflicting immense physical suffering on great numbers of persons and the greatest amount of mental anguish on parents. The two gentlemen to whom the country is so much indebted are Mr. ARTHUR O'CONNOR himself on the one hand, and the President of the Local Government Board, Mr. RITCHIE, on the other. Mr. ARTHUR O'CONNOR, by his exaggeration of language, error of reasoning, absurd abuse of the medical profession, and utter want of sense of proportion in regard to human ills, was kind enough to do service to the cause of vaccination and common sense, albeit, as he tells us himself, he is the son of a physician, and has other relations with a profession whose greatest achievement he is so incapable of appreciating. Let us take one specimen of his statements and his reasoning:—"This vote makes it the interest of hundreds of thousands of educated and refined men to sanction and maintain, and almost to insist upon, the systematic prosecution, fine, imprisonment, &c., of parents, &c." What importance can attach to the words of a speaker who can condense so much error into a sentence as there is in this? Hundreds of thousands of educated and refined men demoralised by £16,000! Let us analyse this nonsense. Probably about one medical man in twenty is a vaccination officer. The nineteen are deprived by the system denounced by Mr. ARTHUR O'CONNOR of the chance of public payment for vaccination; more than this, they are deprived of cases of small-pox, which are far more lucrative to the medical profession than cases of vaccination. Then, to crown all, there are no hundreds of thousands in the profession, but only 25,000 in the three divisions of the United Kingdom. We beg to assure Mr. ARTHUR O'CONNOR that the medical profession is not so easily demoralised. It is only fair to say that several members of Mr. O'CONNOR'S own party in Parliament disclaimed his views. Mr. RITCHIE is as much to be thanked for showing the strength of the case for vaccination as Mr. O'CONNOR is for exhibiting the weakness of it and of those who oppose it. The former gentleman made an admirable statement. The demonstration that but for vaccination 12,000 more children would have died of small-pox in a given year than did die of it was crushing. The champions of vaccination can afford to allow an occasional death from faulty vaccination, though that is so rare an occurrence that men who have been nearly half a century in practice have not seen it. The system of rewards for vaccination has for its object the prevention of such accidents, and the encouragement of the most effective and perfect vaccination. The facts about the case of the great city of Philadelphia come opportunely to hand at this moment. There has not been a single case of small-pox in that city. The control of the disease is due to the use of what Mr. ARTHUR O'CONNOR is pleased to call the "filthy rite" of vaccination. It is stated, says *The Times*, quoting a Philadelphia paper, that if the "health officer of the city receives in his morning mail news of a suspected case of small-pox, he at once sends word to the vaccine physician of the district to visit the suspected house and neighbourhood, and vaccinate all who are not evidently well protected by this operation against the disease. The agents of the board are at once despatched to thoroughly disinfect the suspected premises, and to insist upon their being placed in proper sanitary condition. Later in the day the proper officer is sent to investigate the nature of the case reported. The result is that, whether the case be small-pox or not, vaccination and disinfection are secured." Mr. ARTHUR O'CONNOR, in spite of his exhaustive investigation of the subject, will perhaps be surprised to learn that the enlightened people of Leicester, whom he holds up to admiration, are protected in the same way as those of Philadelphia. The "filthy rite" saves the city. Any case of small-pox occurring in Leicester is immediately reported (see THE LANCET of June 5th), and all the powers of JENNER and vaccination are immediately brought to bear on all exposed persons. All the staff of officials—officers of health, nurses, and sanitary inspectors—surrounding the case are protected by the "filthy rite" doubly performed—that is, they are *revaccinated*. And but for this protection, "dispraised" by Mr. ARTHUR O'CONNOR—"no small praise,"—the plague would spread in Leicester as elsewhere. There is something almost mean in withholding these facts if they are known; and the gentleman who does not know them has no right to take up the time of the House of Commons in September, or any other month, in arguing for or against vaccination. To the credit of the House, Mr. O'CONNOR'S motion was negatived without a division. If any member of the House has still any doubt on the economy of the vote, let him consider the cost of an epidemic of small-pox to any town, the paupers that it makes, and the misery that it entails.

THE recent meeting at Birmingham of the British Association was, both in the scientific and social sense, a great success. The great midlands town spared no labour and no expense, and the inhabitants vied with one another in hospitality to the visitors. Many important papers, accompanied with an unusually small proportion of rubbish, were communicated to the sections, and discussed in a fairly satisfactory manner, considering the limits of time. All the presidential addresses were valuable, even those which were most speculative in their character. Modern inaugural addresses seem to divide themselves mainly into those which present summaries of recent progress, and those which sketch out promising lines for future work. The discussion of details, even details of the highest importance, belongs more properly to the work of the sections, or to the societies which deal with separate branches of science. The latter kind of address is probably the most useful "for the advancement of science," for abstracts of recent discovery can be

Digitized by Google

compiled by anybody, whereas it takes a master to guide others forward.

We have said that all the presidential addresses were good, and several of them were highly speculative, but there was one, that of Mr. CROOKES, in the Chemical Section, which was more important and more interesting than all the others. It was, indeed, a contribution to science which can never be forgotten, and which is not improbably destined to stand permanently as a landmark in scientific history; for in it there was for the first time presented a well-based, intelligible, and coherent hypothesis to account for the genesis of chemical elements, and so for the existence of matter as we know matter. As hypothesis it was put forward and must remain until further discovery dethrones it or raises it to the rank of a theory. Listening to it was listening to the first chapter of Genesis, the dim record of a time "when the earth was without form and void." For it dealt with antiquity, compared with which the earliest geological records are modern history, and afforded scope for scientific thought in a region in which dreams only had before been possible. We came face to face with the primordial matter, the "protyle," to adopt Mr. CROOKES's happy coinage, from which the chemical elements have developed and are still elsewhere in space developing, and found ourselves furnished with a scheme of evolution which gives a rational though hypothetical explanation of many facts which had long tantalized us by being at once simple and incomprehensible. To say that we have solved the enigma of physical existence would of course be absurd. Given the ultimate particles of "protyle" from which elements are generated as compounds are from elements, and we are still no nearer to the infinitely small—are still, indeed, at an infinite distance from it. Infinite space, as infinite time, defies us, and each particle of Mr. CROOKES's "protyle" is perhaps a universe to particles still smaller. But it is much to find our empire of thought and study so greatly extended, and still more to find that rich mines of discovery seem to await us in the new territory.

It is all but impossible in the space allotted to us to give even an outline of the new apocalypse of chemistry which Mr. CROOKES's generalisations, based partly on the discoveries of others and partly on his own elaborate scientific work, present to us, and we can but hope that every man who loves science will study the address for himself. But a few remarks will not be out of place, and may serve to indicate the lines of research which seem opening to chemical science.

The conception of a single element—that is, of a simple matter analogous to the protoplasm of the physiologist—is by no means new to science. It is indeed difficult for the mind to rest satisfied with the idea of an apparently capricious number—say seventy—of elemental forms of matter, some being abundant and some exceedingly scarce which limit creation and are primordially different. But they had to be recognised as elements, and their combining weights, called for hypothetical reasons atomic weights, have been ascertained with greater or less accuracy by the expenditure of an almost incredible amount of human skill and labour. The atomic weights are very diverse, and at first appeared to have no relation to one another. The hypothesis of PROUT, in the early days of exact chemistry, suggested that they were all multiples in whole numbers of the atomic weight of hydrogen. This hypothesis has been a battle-field for chemists. STAS demolished it, but subsequent researches have thrown doubt even upon the position of STAS, that most laborious of chemists. Then it was perceived that numerical relationships, too close to be accidental, existed among the atomic weights; that, for example, the atomic weight of sodium was the mean of those of lithium and potassium—elements which resembled it closely. Other elements, such as nickel and cobalt, which were very similar in chemical character, were found to have almost exactly the same atomic weight; while sulphur, the compounds of which had many points of analogy with oxygen, had exactly twice its atomic weight. Then in 1863 came the important observation of NEWLANDS, which has since proved so pregnant with discovery, that the atomic weights, starting from lithium, formed octaves, or series of seven, in which the eighth resembled the first. This periodic law was extended by MENDELJEFF, whose name is often, but most unfairly, affixed to it; and it is from this law that CROOKES's generalisations started. Adopting but modifying a graphic table recently suggested by Professor EMERSON REYNOLDS, Mr. CROOKES showed that a vibratory or pendulum-like motion of the primordial matter, or protyle, with progressive fall of temperature, afforded a possible explanation of the genesis of elements. At a temperature higher than any known on earth, with a wide swing of the pendulum, hydrogen, or perhaps the helium supposed to exist in the sun, was first formed by condensation. Then followed lithium, glucinum, boron, and the rest, as the temperature fell; until at last, when uranium, with its enormous atomic weight, was generated, the temperature had fallen so low that the elements themselves began to combine into compounds, new elements being no longer produced. Keeping to the pendulum illustration, it will be seen to be possible that at similar points of the right- and left-handed swing similar elements might be developed with atomic weights increasing periodically as the temperature fell. In the diagram which accompanied the paper, which was no fancy sketch, but an accurate representation of the atomic periods on a pendulum the arc of which was diminishing uniformly, the elements are seen in places singularly in accord not only with their atomic weight, but also with their chemical characters, including their atomic combining value, electrical character, and magnetic power. The diagram is quite startling in point of completeness, and certainly shows facts which must be explained by some, if not by the present, hypothesis.

Omitting many other most interesting and important points, we must notice the remarkable evidence obtained by Mr. CROOKES from his own laborious work in regard to the possible variation in the weights of atoms of the same element. Do all the atoms of calcium, for instance, weigh exactly forty, or is forty the average atomic weight, some atoms being as light as thirty-nine and some as heavy as forty-one? By a careful and long-continued system of fractionation Mr. CROOKES appears, at least in one case, to have separated, or as it were sifted, the lighter from the heavier atoms, getting thereby different elements, or, as we might rather call them, different elementary modifications

Digitized by Google

of the same element, quite as unlike one another as, say, nickel and cobalt. Whether this fractionation can be applied to other elements remains to be seen, but in the meantime it presents a working hypothesis, which may end by accounting for the almost though not quite identical atomic weights of some similar elements, and for many other peculiarities which at present are very puzzling. Whether confirmed or modified by subsequent researches, these observations and arguments certainly afford a splendid field for future work. The generalisations, put forward with the utmost scientific modesty, cannot be entirely untrue, although, of course, they may not give us an absolutely correct view of the whole truth as to elementary matter.

IT is impossible to read the published accounts of the last meeting of the Metropolitan Asylums Board without thinking of the lessons which Mr. JOHN MACDONALD teaches in an article he has contributed to the August number of the *Nineteenth Century*. Certainly it is true that "the life of the city, with all its variety of functions, should be like the life of the human organism, one and indivisible." The duties that have to be performed for the proper government of the community must differ widely from each other, but they all have as their object the promotion of the welfare of its inhabitants; and if the machinery which is used for this purpose is to produce the greatest amount of good, it must be guided by one mind which represents, and that directly, the will of the large majority of citizens. Just as one organ of the body has to perform one function and a different organ another, and health is only maintained when some controlling power is exercised which is in intimate communication with all, so, in the body politic, the various authorities which are created to minister to its well-being must be made to work in harmony by some central organisation which brings the work of each into common relation, and ensures that there shall be no friction and no waste of power in the efforts that are made.

Birmingham, we learn, was not many years ago governed by a number of parochial bodies, which all doubtless existed for the one purpose of bettering the condition of the inhabitants of the town; nevertheless, this end was not attained, for there was no bond which sufficiently united them. This want was at length supplied, and one body was created, elected directly from the people; and, as a result, a municipal spirit came into existence which has, in the course of comparatively few years, solved at any rate some of the most important problems of social life. Thousands of fever-haunted human piggeries, misnamed houses, have, we are told, been swept away. Birmingham has the control of her own police, her own gas, her own water, has built herself museums and free libraries; in short, with the exception of public education, the Corporation, representing in very thought the wishes of her citizens, has full power to deal with almost every subject that can reasonably be administered by a municipality. The local authority in consequence draws to itself men of the highest standing, all of whose actions are exposed to a public criticism that is the best safeguard of the public interests.

London is much in the position of Birmingham years ago. Divided into parishes, each with numerous boards having different functions, there is hardly one for which it can be said that it is an honour for the meanest of her citizens to belong. The actions of these bodies pass unobserved, unless some rare circumstance may for a while bring them under public notice. London has no control over police, gas, or water; even the boards whose jurisdiction extends over the whole metropolitan area can in no sense be said to represent the thoughts or wishes of the inhabitants. The Metropolitan Board of Works is but a vestry of vestrymen. The Metropolitan Asylums Board is but an enlarged board of guardians, with a sprinkling of members who are not even elected by the people whose money it is their duty to spend. The latter board cannot therefore altogether be held to represent the wishes of London, and every important step they take is the subject of objection by other bodies, who in their turn claim to represent local feeling and interests. Thus the recent determination of the Asylums Board to erect a permanent hospital at Darenth has been matter for protest by the various boards of guardians, and the Local Government Board have decided not to allow any but a temporary institution to be constructed. We can sympathise with this decision for the reason that it implies that the present method of small-pox hospital construction is not approved, and that no further hospitals of a permanent character will be erected in a manner similar to those which have been fully shown to be a cause of disease to the neighbourhoods in which they are placed; but this continual warfare between metropolitan local authorities is to be deplored. It is but too clear evidence of failure in metropolitan government.

London, it must be admitted, is not altogether comparable with Birmingham. Birmingham has but a tenth of the population of London, and the remedy that has been found successful for the smaller town might be less effectual if applied to the great city. Whether the difficulty is to be met by the constitution of one or of several municipal bodies, having control over the whole of London or of their respective smaller areas, is a matter for consideration.

IN a recent issue we drew attention to some of the legal aspects connected with the supply to a town of a water containing sufficient lead to produce definite symptoms of lead-poisoning amongst its consumers, and we now revert to the same subject in its general and chemical aspects, in connexion with a highly interesting report that was some time back issued by Dr. SINCLAIR WHITE, medical officer of health, on the action of the Sheffield water on lead communication pipes, and its effects on the health of the community.

During the summer of 1885, Dr. SINCLAIR WHITE'S attention was drawn to several cases of chronic lead-poisoning in the borough, and it was observed that they not only occurred amongst persons whose trades did not expose them to any such result, but that the drinking-water to the houses in question in each case contained sufficient lead to account for the mischief. The Sheffield water, it would appear, is derived from two sources—namely, first, from the hills about Redmires; and, secondly, from hills around Strines and Agden; the two services being stored in different reservoirs, and being so delivered to the community that it was at once shown that it was the Redmires water which was alone doing mischief. All the mains in the borough

Digitized by Google

are of iron, and water drawn from these mains was found to be free from lead, whereas such Redmires water as had passed through the universally prevalent lead communication pipes was found to be contaminated; that which had stood in the pipes all night being most affected.

The gathering-grounds of the two services are in many respects similar, both being peaty, with shale containing iron pyrites and millstone grit beneath the surface. But the water from Redmires was found to be distinctly acid, the acidity varying in the several streamlets leading to the reservoir, but increasing very materially as the hill was ascended, and being at its greatest where the water was found to be lying in stagnant depressions on the surface of the peat. At Strines, however, the peat is less abundant, and is drier; fine sand frequently comes to the surface, and owing to the configuration of the gathering-ground, there is less tendency for the water to stagnate in pools.

The precise reasons why certain waters exercise a solvent power on lead, and this at times intermittently, are involved in some obscurity, and hence it is that special importance attaches to the record of the investigations made by Dr. WHITE to explain the occurrence in the case of the Sheffield water, and the special incidence of the mischief on the consumers of the Redmires water. In the first place, the source of the free acid is considered in connexion with the production in the atmosphere around Sheffield of sulphur dioxide by reason of the exceptional consumption of coal in the borough; but this is for various reasons set aside. One reason is that the reservoirs for the two services are practically adjacent, and yet only the water of one exhibited the acidity in question. Then, again, the oxidation of the iron pyrites in the gathering-ground would impart to the water free sulphuric acid. This view was, after consultation with eminent chemists, held by several authorities to be the actual cause; the iron pyrites, on exposure to moisture and oxygen, decomposing with the formation of free sulphuric acid. It is true that an insoluble sulphate of lead would be the result of the action of such a water on lead pipes; but, as is pointed out in the report, the insolubility of the lead sulphate is only relative, some waters taking it up in sufficient quantity to produce poisoning. Another view as to the source of the acidity is also entered into, and it is based on the fact that the decomposition of vegetable substances, such as wood, leaves, peat, and vegetable mould, gives rise to the formation of ulmic and humic acids. Now the Redmires gathering-ground is rich in organic matter, much of which is peat, and its configuration tends to the exposure of the water in pools to the influence of this peat; and not only so, but the Redmires gathering-ground differs from the Strines gathering-area precisely in those conditions which tend to favour the production of any such acids as those referred to. It must, however, be admitted that the collecting grounds at Strines are also more deficient in iron pyrites than those at Redmires, and that if the production of sulphuric acid from this substance is at the root of the mischief, the Redmires water would similarly suffer most. Unfortunately, the amount of free acid obtainable from the water was not sufficient to enable the borough analyst to determine its nature, or indeed to decide whether it was of organic or inorganic origin.

Whichever of the two latter views referred to in the report affords the correct interpretation of the occurrence, it should be remembered that summer weather, which was the period when the mischief first became obvious, would, by reason of the increased stagnation of water in pools during periods of drought, tend to increase the evil. It is quite possible that, since attention has now been definitely called to the occurrence, the existence of lead-poisoning by water in Sheffield may hereafter be found to account for symptoms which have hitherto been obscure in their origin, and that more attention will be given to the conditions favouring the process. But we trust that, even with waters collected from such a gathering-ground as that from which Sheffield draws its supply, nothing like a condition of permanency attaches to the water in this matter of lead solution, and that by careful investigation of the circumstances under which the facility for taking up lead increases or decreases we may come to learn something more as to the circumstances which enable such waters periodically to dissolve this substance. In the meantime Dr. WHITE has ascertained that the solvent action of the water upon lead is practically destroyed by keeping it in contact for a time with freshly broken surfaces of limestone, and that, even when the lead has been taken up many of the domestic filters in current use entirely remove it.

Annotations.

"Ne quid nimis."

THE BIRMINGHAM MEETING AND DIRECT REPRESENTATION.

THE number of candidates for the direct representation of the profession is growing day by day in a somewhat haphazard sort of way. It is clearly desirable that the profession should have a variety of candidates to choose from; but it is equally so that a candidate should come forward or be brought forward in a somewhat systematic manner. A committee should be organised for his election, and responsible officers should be named representing his committee. Less than this amount of trouble scarcely shows seriousness on the part of the candidate or a proper respect to the profession whose votes have to be secured. If the chances of success do not warrant this amount of trouble, it will be kind on the part of gentlemen not to complicate the difficulties of the profession by lengthening the list of candidates. The reasonableness of our suggestions will be more easily admitted if our readers will study the report we give elsewhere of what happened at a meeting in Birmingham. The promoters of that meeting were no doubt actuated by a laudable desire to assist the profession in choosing fit candidates. They were aware of a certain suspicion of cliquism, or caucusing, and took great pains to rise above all such charges and to make their meeting representative of the whole country. Dr. Carter said at the meeting that 343 responses had been received to 1167 invitations issued, representing 161 towns. But evidently 343 responses cannot represent 17,000 practitioners. And an actual meeting of only thirty-two is still more conclusive proof that the profession will have to show its mind in other ways. The supporters of any candidate will not be able to rely on any central or single meeting. Our profession is not organised for election purposes. Happily so! At the Birmingham meeting the first resolution seemed to commit the meeting to an immediate selection and requisition of three fit and proper persons. Nine or ten were nominated and a few were seconded. But by the time the

Digitized by Google

nomination was finished the meeting had become still more attenuated, and it was finally resolved to send the names nominated to members of the General Committee on a post-card, and to adopt those having the largest number of votes as the candidates of the committee. This course was approved by a majority of 11 to 3. We can scarcely doubt that the promoters of this meeting will be ready to admit its failure, and will not seriously prosecute their well-intentioned labours. They might take this comfort to themselves—that if they have failed no one committee is likely to succeed. About a dozen names are now before the profession in England in a more or less formal way, and it cannot be denied that at least half of these would make excellent representatives. The candidates are—Dr. Taaffe, of Brighton; Mr. Bullock, of Isleworth; Mr. Wheelhouse, of Leeds; Dr. Glover, of London; Sir Walter Foster, of Birmingham; Dr. Richardson, of London; Dr. Dolan, of Bradford; Mr. Hart, of London; Dr. Bridgwater, of Harrow; Dr. Holman, of Reigate; Dr. Balding, of Reigate; and Dr. Morris, of Spalding. The friends of these gentlemen, on local committees, and with proper confidence in their cause, will do what any one committee cannot do any more than any one Association. The profession, for the first time, feels itself with a "free hand," and it seems determined to use its freedom and to rebuke the fears of those who said it would be led in an undignified way.

RECENT DIARRHŒA MORTALITY IN LARGE ENGLISH TOWNS.

THE mean temperature of the fortnight ending Sept. 4th showed a marked increase upon that which prevailed in the preceding six weeks, and it is not surprising to find a considerable increase in the mortality from diarrhœa recently recorded in the largest English towns. The fatal cases of diarrhœa registered in the twenty-eight large towns dealt with in the Registrar-General's weekly return, which had increased from 530 to 710 in the preceding four weeks, further rose last week to 995, and considerably exceeded the number returned in any previous week of this summer. It is worthy of note that the mean temperature of the two weeks ending September 4th was almost identical with that of the fortnight ending July 10th, but that these two periods of high temperature appear to have affected the mortality from diarrhœa in London and in the large provincial towns in a very different manner. In London the earlier hot period caused a rapid increase in the deaths from diarrhœa from 43 in the last week of June to 411 in the last week in July, after which the weekly recorded deaths from this cause steadily declined to 176 in the week ending the 4th inst., this decline being apparently uninfluenced by the marked increase and excess of temperature during the fortnight ending on that day. In the twenty-seven provincial towns, on the other hand, having an aggregate population differing but slightly from that of Registration London, the deaths from diarrhœa increased from 43 in the last week of June to 804 in last week, the increase due to the first hot period being very small compared with that due to the more recent hot period. In the week ending July 31st, when the maximum diarrhœa mortality was reached in London, the annual death-rate from this cause was equal to 5·2 per 1000 in the metropolis, whereas in the aggregate of the twenty-seven provincial towns the mean rate did not exceed 2·5. The rate from the same cause last week, however, did not exceed 2·4 in London, whereas it was equal to 8·4 in the aggregate of the twenty-seven provincial towns. Epidemic diarrhœa mortality usually occurs in London before it attacks the provincial towns, although why this should be the case has not been determined. Neither is it easy to explain why the recent fortnight of hot weather has caused no increase in the diarrhœa death-rate in London, although it has produced such fatal results in so many of the large provincial towns. That temperature is not the only, or even the most powerful, factor in the causation of infantile diarrhœa may be fairly inferred from the following figures. The annual death-rate last week from diarrhœa, according to the Registrar-General's weekly return, ranged from 1·2 in Bristol, 1·8 in Huddersfield, and 2·4 in London, to 11·3 in Birmingham, 12·0 in Leicester, 12·4 in Preston, 12·8 in Hull, and 15·3 in Norwich.

CLINICAL EXAMINATIONS AND DANGER TO PATIENTS.

CLINICAL EXAMINATIONS on actual patients in hospital wards are, of course, of the utmost value in testing a student's ability to recognise and treat disease; but when, from whatever cause, they are so conducted that the patients suffer seriously from the processes to which they have been subjected, there is no doubt that some abuse of a very excellent system must have been permitted. A case has occurred in Brussels in which a surgical examiner, forming one of the central examination jury, while testing the candidates' knowledge in the Hospital of St. John, owing doubtless to some misunderstanding as to the nature of a case, removed an antiseptic dressing which had been personally applied with more than usual care by the visiting surgeon after an operation for suppurative inflammation of the right knee, so that when the patient was visited next day his condition was greatly changed for the worse, and subsequently the leg had to be amputated in order to save his life. The surgeon naturally reported the circumstances to the "Conseil des Hospices," the authority by which the Hospital of St. John is managed, and the consequence was that a regulation was made, ordering that during clinical examinations one of the medical officers in charge of the ward shall in future always be present. This regulation, which is asserted on the one hand to mean merely that examiners shall be informed what patients may, without injury to themselves, be made use of for examination purposes, and on the other to imply a desire to exercise some sort of surveillance over the proceedings of the jury, so offended the examiners that they decided not to hold any more clinical examinations in any of the institutions under the management of the "Conseil des Hospices," and betook themselves to the Hospital of Molenbeek St. Jean, which is under a different authority, and where the jury is "treated with the consideration which is due to it." The whole affair has been discussed pretty freely in Brussels, letters on the subject being published even in the daily press, and several somewhat contradictory accounts having appeared. The above is, however, we believe, a substantially correct statement of the facts. Considerable tension has unfortunately existed amongst the medical teachers in Brussels for some time past, and the incidents above related may possibly be to some extent due to that cause, and have of course had the effect of intensifying it. Surely some *modus vivendi* might easily be found which would enable our excellent *confrères* to compose their differences.

MASTICATION.

A CURIOUS controversy is in progress as to the need or value of "biting one's food." Strangely, as it must appear, there are some, who should be authorities, ready to affirm that it is futile to take the trouble to use the teeth with which nature has provided man in common with most other animals apparently for the special purpose of cutting and grinding his food. Little, if any, weight is attached to the evidence of facts in this dispute. The existence of the dental apparatus counts for nothing. Nor does it go for much that movements of the jaw promote the insalivation of the food. In short, mouth digestion is treated as a myth or

Digitized by Google

little better. What are we to understand by all this? Is it one of the early fruits of that attempt to popularise the science of physiology which has been so persistently and unselfishly made by the medical profession in the supposed interests of public health and the prevention of disease? We do not incline to mingle in the fray, just at present at least. Let the dispute go on and be fought out to the bitter end. Meanwhile, we counsel all who care for their comfort, and who do not desire to develop the worst form of dyspepsia, to continue the practice of mastication as before. As a matter of fact and experience, a liberal use of the teeth in feeding is one of the essentials of easy digestion, and though we are not prepared to assert that it is necessary to bite each morsel of meat precisely twenty-five times, it is better to err on the side of masticating too much than on that of not masticating enough: first, to divide the food and crush its fibres and particles generally, and secondly, to mix it so thoroughly with the secretion from the salivary glands that not only shall the act of deglutition be rendered easy, but that the food when it enters the stomach shall have been properly prepared for digestion in the gastric juice.

THE BACTERIOLOGY OF WATER AND AIR.

IT is well known that the atmosphere and water generally contain many forms of micro-organisms; but the conditions that are favourable to the growth of these low forms of life and the causes which lead to the development of toxic agents are a new field of investigation whose elucidation is a matter for future observation. Messrs. Crookes, Odling, and Tidy, in their official report on the persistence of bacterial life in water, have added to our store of facts so far as water is concerned. These observers have employed sterilised distilled water, in which a definite quantity (1 part in 150 of water) of peptone fluid, swarming with an active sporeless growth of the splenic fever bacillus, was introduced. After the lapse of two hours an artificial cultivation of the infected water resulted in an abundant and characteristic growth of the bacillus, from which fresh cultivations could be produced. The results after the expiration of three hours were uncertain, and when a longer time had elapsed no cultivation could be obtained. The water used by the experimenters was of greater nitrogenous contamination than Thames water, and therefore highly suitable for the growth of the bacillus; and yet after the expiration of six hours the bacillus appeared to have effaced itself. On the atmospheric side of bacteriology, we have the observations of M. Miquel made on the air around Montsouris. An increase in the number of bacteria in the air was observed to accompany a rise in the barometric pressure and an augmentation also occurs in the summer months, though a sustained high temperature tends to lessen the number of bacteria. A low hygrometric state of the atmosphere was found to accompany the maximum number of bacteria, and a maximum number was also associated with a calm or slowly-travelling wind. The greatest number of maxima occurred with a north-east wind, and the least with a south-west wind. The presence of a large amount of ozone in the atmosphere went side by side with a reduced number of microbes. The observations at Montsouris have been carried on for a period of five years, and it has been estimated that the average numbers of organisms in a cubic metre of air, during spring, summer, autumn, and winter respectively, are 495, 650, 380, and 260. February gave the lowest average, 165, and July the highest, 700. The atmosphere of Paris is altogether different, for the average number of organisms in a cubic metre of air taken from the Rue de Rivoli was 3480, but the minimum and maximum occurred in February and July respectively, as at Montsouris. The number of organisms was very much lower in the year 1884 than in 1881, and this fact was associated with a greater efficiency in scavenging in 1884, and also with a lower death-rate from zymotic diseases. Dr. Miquel has also made a few observations on the atmosphere of London: only 240 bacteria being found in a cubic metre of air during the month of June. This comparative poverty of bacteria is attributed to the nearness of London to the sea and to the moderate height of the houses not preventing the purifying influence of the wind. What a tremendous contrast the atmosphere of the ocean and mountain presents with that of the wards of the Hôpital de la Pitié in Paris; for the former never contains more than an average of one bacterium per cubic metre, whilst the latter has been known to hold in suspension as many as 97,000 organisms in a cubic metre of air!

CHOLERA ON THE NEAPOLITAN RIVIERA.

ON this subject our correspondent in Rome writes:—The outbreak at Torre Annunziata is now describing the descent of the parabola, and the panic that was causing a general stampede from that lovely seaboard has died away. The significance of the visitation lies in the utter want of preparation on the part of the Neapolitan municipality for the spread of the disease from its latest outpost not ten miles off. When fugitives from Castellamare and Torre Annunziata and the other townships along the bay came trooping into Naples, *en route*, if possible, to Rome and Tuscany, then only her sanitary authorities bestirred themselves, with the result of revealing to a scandalised public how little of the promised hygienic improvements had been effected. Two years ago, after the fearful explosion of cholera in the city, nothing was heard of but the immediate measures that were about to be taken for the clearing away of the rookeries, the amelioration of the drainage system, and the introduction of pure water. With the exception of this last, not one of these improvements, sanctioned by Parliament and expected by the country, has even been begun! The *Opinione* describes with bitter irony the feverish haste with which the Neapolitan sanitarians are turning out the court and cellar population into the street, often to contract other maladies than the expected one; flushing drains and whitewashing alleys, in the belief that the malady is as open to being scared as themselves! "To-day," it says, "all is activity, all is exaggeration; when the danger passes or diminishes there is the old relapse, with inertia, neglect, abuses." Doubtless, the plain-spoken journal, charged with salutary home truths, was duly delivered at the municipality, reeking of carbolic acid, although its point of departure was Rome, where well-timed precaution has long kept the enemy at bay!

"EXEAT BRUMMAGEM."

THAT scientists are fastidious and prone to hypercriticism is one of the fallacies of which little should be heard after the recent meeting of the British Association at Birmingham. Granting that the midland metropolis was at its best, that political differences were buried, and all the resources of the municipality and the people placed at the disposal of the learned visitors, these, irrespective of sex and section, were certainly in the most complimentary mood. The concluding meeting, held in the Town Hall, under the presidency of Sir William Dawson, was phenomenal, almost as much for thorough unanimity as for thronged attendance. The Mayor, Alderman Martineau—a lineal descendant of Martineau, the great Norwich surgeon,—with all his experience and tact, seemed positively embarrassed by the compliments showered upon him and his corporation by Professor Bonney and Capt. Douglas Galton. Sir Frederick Goldsmid and Dr.

Digitized by Google

Gladstone, F.R.S., were loud in praise of the financial success which the thousands of local associates had rendered possible; but it was reserved for Mr. Pengelly to utter a Pickwickian grumble. He had just before been wittily discussing in the Geological Section on a Scrobicularia bed containing human bones at Newton Abbot, but could not repress a feeling of disappointment. He had travelled thither in the belief that where they stood he should find "Brummagem." But he had not met with the article at all. The town buildings, the manufacturing exhibits in Bingley Hall, the educational institutions—nay, even the coffee, were intrinsically good and artistically fine. The bare fact is that very few communities have advanced at such rapid strides as Birmingham has done during the last few decades; and everyone interested in human progress may gratefully and hopefully say "Floreat Birmingham."

EVIDENCE OF INSANITY.

A GOOD rule of practice in regard to stating the ground of an opinion is to "never give reasons." There is great need of something approximating to this reserve in respect to the evidences which lead to the formation of a judgment that any particular person is insane. We do not for a moment doubt the fact that the hawker arraigned, and, in the event, convicted, before the Autumn Circuit Court of Judiciary for Forfarshire, for certain diabolical offences, was of unsound mind; but it must be confessed that the evidence adduced in support of the opinions formed by two excellent and most competent medical authorities was not only wholly inadequate but singularly inconclusive. Setting aside such presumptive evidence as the facts that his mother's father had been mad and had been put in a straitwaistcoat, that his mother's brother was silly and one of her own children had epileptic fits, and that the prisoner himself had suffered much in early life—as when he had scarlatina with delirium followed by deafness, whooping-cough of long duration, and a fall from a height of twelve feet on the back of his head, followed by unconsciousness for two days—the chief proofs of insanity seem to have been that he had a very imperfect notion of how the simplest accounts ought to be kept, that he could not count above twenty-nine, and that when asked his age, he said "nineteen or going in twenty," which, it was contended, was two ways of stating the same thing! There was no delusion, and nothing except a good deal of insensibility in regard to his crimes, which might either arise from a deficiency in the recognition of right and wrong or from anything else. Obviously, it could not be expected that a court of justice would be satisfied with evidence of this sort, when the plea of insanity was raised—not very wisely as it appeared—to shield from punishment a scoundrel who was alleged to have committed two rapes and other abominable offences against the person. We venture to think it would be more discreet in cases of this class, where the medical judgment of insanity is based on general and not on special grounds, to affirm the opinion without particularising reasons, rather than to bring forward evidence which is clearly not of a nature to be tested by unskilled jurors. We do not for a moment question the entire accuracy of the opinion expressed by the medical witnesses in this case. These gentlemen are so highly qualified to form a judgment on the issue raised that no member of the profession can hesitate to accept and adopt their opinions, but this fact only makes it the more regrettable that no better evidence should have been forthcoming in support of their views. In truth, it must often happen that good presentable proofs of insanity are wanting in cases where no room for doubt exists. The perception of disease is a distinctly medical function, whether the malady be one of body or mind. No sensible layman would expect a physician to adduce such evidence of the existence of what is called physical disease as would be available for the formation of a non-medical judgment. Why should laymen expect to be furnished with evidence of a nature to convince a person having no special knowledge of mental disease that it exists in any particular instance? It would be more rational and dignified if medical witnesses simply stated their opinions without giving reasons when requested to do so, and simply avowed their inability to place the grounds of a diagnosis before a lay court. In the course of a recent trial this side of the Tweed, a learned judge said, in reference to the evidence of an expert in caligraphy, that when once the indications discovered by the expert were pointed out, the unskilled observer was as competent as the expert to determine their value. We accept this ruling, but the indications of disease, whether of body or brain, are not of a nature to be thus brought under the cognisance of the unskilled observer. The medical witness is rather the "sworn interpreter" than the "expert" when he construes the evidences of disease and gives the result in a language "understanded of the people." If this were more generally recognised, there would be fewer experiences, in courts of justice, which are not merely disappointing but humiliating, and which it is most undesirable, on many accounts, to multiply.

TRAUMATIC PLEURISY.

DR. SEVED RIBBING reports, in the Swedish *Eira*, amongst a number of instructive cases, the following one of traumatic pleurisy. A man, who had received a blow on the right side of the thorax in a drunken quarrel, was admitted into the Cimbrishamn's Hospital with the ordinary signs of pleurisy with effusion. The cavity was consequently aspirated, the puncture being made in the eighth intercostal space just below the angle of the scapula. The signs of fluid returning, it was decided to open up the cavity. This was done by an incision in the same situation as that in which the aspiration had been performed, and a quantity of thick fibrino-purulent matter evacuated, a large French œsophageal sound being used for drainage. Two days after the operation it was noticed that the integuments and superficial muscular layer around the shoulder-joint flapped like a curtain at each inspiration. As this pointed to the existence of an abscess cavity communicating with the chest, a sinus was searched for and discovered running upwards from near where the opening into the thoracic cavity had been made. This sinus was laid open, and, together with the chest, carefully drained and washed out with carbolised water. The quantity of fluid which came away diminished daily; the temperature, which had been high, sank; and in three months' time the man was discharged cured.

VACCINATION IN EAST AFRICA.

A CORRESPONDENT, writing in *The Times* of Wednesday, quotes from a letter recently written in East Africa as follows: "The small-pox is very severe now in the Bondei Country. The natives are offering three dollars apiece to be vaccinated; but, most unfortunately, our lymph supply was destroyed in the late fire at Maglia. One man offered twelve dollars—i.e., nearly £2 10s. of our money. They have such faith in it, for none of the people who were thoroughly vaccinated have suffered at all from small-pox, while members of the same family who were not vaccinated were seized with it." It is the old story over again. When small-pox is prevalent in an unvaccinated community, vaccination is valued, and no complaint is heard other than that which is caused by the scarcity of lymph; but when a community is more or less protected by vaccination from death by small-pox, then its value is forgotten, and the agitators of the time assert themselves very loudly. There is little doubt

Digitized by Google

that if, instead of a compulsory law, difficulties had been put in the way of vaccination, the same individuals who now describe vaccination as a "huge and deplorable delusion," would have been loud in their demand for a removal of the restrictions. But these agitators must forgive our statesmen if they refuse to submit the country to a wholesale destruction of human life for the purpose of teaching them the lesson they need to learn.

DIAPHRAGMATIC HERNIA.

Il Bullettino della Reale Accademia Medica di Roma (May, 1886, p. 245) contains a description by Dr. Ferraresi of a diaphragmatic hernia revealed in the necropsy of a young man who had died with symptoms of intestinal strangulation. On surface inspection of the well-nourished body, it was noted that the abdomen was only slightly swollen; the left half of the thorax was broader and more prominent than the right, and the left intercostal spaces dilated. Percussion revealed an area of absolute dulness over the whole left chest, excepting the subclavicular triangle, which yielded tympanic resonance. On opening the abdominal cavity, the coils of small intestine, slightly reddened, presented patches of fine basal injection. Carefully opening the thorax, the left pleural cavity was found filled with a bloody liquid, on giving exit to which the lung, compressed and driven upwards, became visible, the heart being displaced to the right. Besides the liquid already referred to, the pleuritic cavity contained numerous coils of intestine enormously distended, of dull red colour; the serous membrane was opaque, rough, and studded with numerous hæmorrhagic spots. The stomach was displaced to the right, with the great curvature turned towards the abdominal wall. Holding aside the stomach and the small intestines, still retained in the abdomen, it was observed that the splenic angle of the colon and a good part of the jejunum passed into the pleural cavity through a hole in the left inferior half of the diaphragm at a point corresponding to the normal position of the heart's apex. The descending colon was much contracted. With great difficulty, and after repeated punctures, it became possible to reduce the coil of colon, a piece of omentum, and the displaced small intestine. The hole in the diaphragm was oval, rather more than an inch in diameter, surrounded by a strong, thick, fibrous ring. The gastro-colic omentum which followed the displaced coil was shortened, and adherent posteriorly to the margin of the fibrous ring.

THE INFLUENCE OF SMALL-POX HOSPITALS.

ON Saturday last Mr. Justice Stirling heard, in the High Court of Justice, an application on behalf of a dairyman living at New Windsor for an injunction to restrain the Mayor and Council of New Windsor and the guardians of Windsor from erecting hospital tents for small-pox patients on certain meadows in proximity to his dwelling. The case presented but little medical interest, the proceedings apparently being taken in anticipation of the extended use of a temporary hospital which had been erected on the site. The medical evidence for the plaintiff, it seems, did not go beyond placing before the Court the information contained in recent reports of the Medical Officer of the Local Government Board, which pointed out the effects of aggregation even of a small number of patients suffering from small-pox in its acute stage, and showing that the hospital was not constructed in the manner suggested by the Royal Commission, so as to ensure the destruction or purification of the air in the wards. The hospital subsequently did not receive more than seven cases, and the site not being found suited for hospital purposes, it was determined to abandon it and receive no more patients into the institution. Under these circumstances Mr. Justice Stirling refused the application. The case is instructive as showing that, if local authorities determine to erect hospitals for this purpose near inhabited houses, they will probably meet with opposition, unless they construct them in the manner indicated, or limit their use to a very small number of cases.

MANAGEMENT OF THE THIRD STAGE OF LABOUR.

DR. A. R. FISHER, assistant in the obstetric clinic of Professor Slavianski in Kharkoff, has made a large number of observations with the view of determining the relative advantages in the third stage of labour of Credé's system of gentle manipulation or massage of the uterus, and the method of forcible expression of the placenta by powerful compression of the uterus. His statistics point decidedly in favour of the former method. In 493 cases where Credé's method was employed post-partum hæmorrhage occurred twenty-five times, while in 183 cases where expression was resorted to it also occurred twenty-five times; that is to say, the hæmorrhage cases were 5 per cent. with Credé's method, and 13 per cent. with the expression method. Again, the retention of pieces of membrane occurred less frequently with the former than with the latter mode of treatment, the percentage of cases in which this occurred being 5·7 and 7·4 respectively. The relative proportions of the occurrence of pyrexia, by which was understood any rise above 38° C., the temperature being taken three times daily, were 38·3 per cent. and 46·4 per cent., and the cases in which puerperal complications supervened were also fewer after Credé's method than after the more violent procedure, being respectively 5 per cent. and 9 per cent. A diagram is given with the author's paper, which is published in the *Russkaya Meditsina* of August 10th, showing that the process of the involution of the uterus is perceptibly quicker, at all events during the first week, in cases where Credé's method has been used, than in those where the placenta has been expressed. Dr. Fisher concludes with a general eulogy of Credé's method, as being the most rational and successful plan of treating the third stage of labour, and withal so simple that every doctor, and indeed every properly instructed midwife, should practise it habitually.

LARYNGEAL PARALYSIS IN LOCOMOTOR ATAXY.

AN interesting case of locomotor ataxy was recently in the Birmingham General Hospital, under the care of Dr. Robert Saundby. The patient, in addition to the ordinary symptoms of the disease—e.g., ataxic gait, loss of patellar reflexes, inability to stand with his eyes shut, &c.,—complained that he could not lie down in bed on account of difficulty of breathing. When he was induced to assume a horizontal position, he was seized with an alarming suffocative spasm. His voice was a little hoarse, but otherwise normal. On laryngoscopic examination, both cords could be seen lying in the middle line in the position of phonation, no motion being perceptible on inspiration. The movements on phonation were normal. A few days later a very severe attack of dyspnœa almost proved fatal, and tracheotomy, which had previously been advised but declined, was performed at once. The man died a few hours afterwards in a fit of coughing, a large amount of pus welling up into the trachea. As permission could only be obtained for a partial necropsy, the head could not be opened. The spinal cord showed well-marked sclerosis of the posterior columns. Cases of this kind are rare, but examples have been recorded by Dreschfeld, Semon, and Charcot. Dr. Saundby remarked that such cases possibly occur more frequently than records

Digitized by Google

of them might lead one to suppose, and that in all cases of bilateral paralysis of the abductors of the larynx other signs of locomotor ataxy should be sought for; conversely, all cases of the latter disease should be examined with the laryngoscope, as it is only when the paralysis is complete that urgent symptoms are present as they were in the case under notice.

LUNACY LAW REFORM.

THE objections taken to the vote for the Lunacy Commission in England were well grounded. The authority at Whitehall is not worth a tithe of the money devoted to its maintenance. The existence of a body bearing the name of a Commission is doubtless of some moral weight, and for this the public may be willing to pay a small sum. We will go further, and admit that as the labourer is worthy of his hire, without regard to the real value of his services, the gentlemen who hold office, whether as legal or medical commissioners, are entitled to their stipends; but for all the good actually done by the Commissioners in Lunacy, a couple of clerks at £500 a year, to register the certificates sent in if the forms be properly filled up, or to return them for correction if irregular, would be as fuliy effective as the whole staff maintained at a cost to the taxpayers of £15,000 yearly. The Government announces another Lunacy Bill. We do not at the moment remember how many Bills have been introduced during the last ten years, but the number must be considerable. Will the now promised measure be any better than its predecessors? We think not. The subject is so thoroughly in the hands of the red-tapists that there is absolutely no reasonable ground for hoping that a satisfactory measure will be introduced. Nothing short of a complete reconstruction of the law relating to the sequestration of lunatics, placing the treatment of insanity entirely on the footing of a medical care and cure of the insane, and safeguarding the liberty of the subject by taking the right of incarceration wholly out of the hands of private persons, can be satisfactory; and so large a measure of reform as these changes would involve we fear there is not the slightest reason to anticipate.

THE ELECTRIC LIGHT AND THE EYE.

PROFESSOR COHN, whose works on the Hygiene of the Eye are so well known, has lately delivered a lecture in Breslau upon the Action of the Electric Light upon the Eye. That this light sometimes induces inflammation both of the internal and external tunics, when incautiously used, is indubitable. Cases have occurred in which retinal inflammation and sclerotic congestion have followed protracted exposure to arc lights, and this arises in all probability from the great concentration of the light of such burners, the field of vision otherwise being dark, a condition that is very different from that of diffuse daylight, which we know to be free from danger, though the light is certainly as intense, whilst the field generally is much more perfectly illuminated. Professor Cohn remarks that artificial light should not be dazzling, that it should be supplied bountifully; it should not heat the eyes, and it should burn steadily. Arc lights, he thinks, in order to fulfil the first condition, should be surrounded by a globe of white or ground glass, which deprives it, however, of about 30 per cent. of its illuminating power. Even with this diminution its penetrating power is greater than gas of equal brightness, because the same quantity of light is concentrated in a smaller space. According to the investigations of Voit and Ranke, at Munich, the light from a glow lamp of Edison is seven times brighter than that of an Argand gas lamp, and twelve times brighter than that of a fan-shaped gas light. The glow light will therefore excite the retina from seven to twelve times more than a gas flame of equal brightness. If the electric light be used, care should be taken that it is not too weak, for in that case books or work must be held close to the eye, and there is abundant evidence to show that such approximation is a fertile source of short-sightedness. Professor Junge of Zurich informed Professor Cohn that the local reading society had given up the use of the glow-lamps because with the power supplied the illumination was too weak. To obtain a sufficient light in this instance a dynamo of double the existing power would have had to be erected, and the expense then would have been double that of the gas. The absence of heat is a great point in favour of electric lighting, for a hot flame in proximity with the eye dries up the moisture on the cornea, and, after producing a feeling of dryness, is almost certain to lead to congestion of the vessels which surround it, and to pain and headache. Professor Cohn himself demonstrated some time ago that the rise of temperature 8 in. from a gas flame is double that at the same distance from a glow lamp of equal brightness. Additional advantages which are possessed by the electric light are the absence of carbonic acid gas and other products of combustion. The examination of the air of theatres in which gas is burnt with that of theatres which are illuminated by electricity shows in the latter less carbonic acid and no smoke, and that the quantity of moisture added is much less, whilst the temperature is lower. The Professor points out the importance of the electric light being steady. When a flame flickers the intensity of the light is undergoing constant change—a condition to which the retina is very sensitive, as is shown by the disagreeable sensation felt in walking along an open wooden railing on the other side of which the sun is shining. On this ground the glow-lamp is superior to the arc light. In either case the strength of the current should be sufficient to make the light steady and strong.

CLINICAL TEACHING AT MELBOURNE.

WE learn from the *Melbourne Argus* that on July 22nd the Premier received a deputation of students of the Medical School, who had taken this unusual but legitimate course of urging on the Government to insist that out of the grant made to the Melbourne University the sum of £500 should be applied to the appointment of clinical lecturers. Mr. Gillies said that at the request of the students he had invited some members of the University council to attend, and they had forwarded him a resolution to the effect that it would not conduce to the discipline of the University for the council to meet their own undergraduates and argue with them in public on the course the council had thought it necessary to pursue. Mr. Gillies could not take any exception to this resolution; he would hear what the students had to say, and would afterwards communicate with the council. Mr. C. P. W. Dyring, B.A., read a statement prepared by the committee of the Medical Students' Society, which dealt with the importance of adequate clinical teaching and the necessity for it, every examining body requiring certificates of attendance on such lectures. The University authorities required this, and the rules of the Melbourne Hospital provided for the appointment of special clinical lecturers by the council of the University from among the members of the medical and surgical staff. In 1883 a deputation from the council applied for an increased endowment, specifying among the immediate requirements "two clinical lecturers, medicine and surgery, £500." Parliament voted an increase of the grant by £2000, and the University calendar of 1884-85 showed that the council recognised that the sum of £500 was voted specifically for the payment of clinical lecturers, who were appointed in 1884; but in the following year the council departed from this system. No clinical lecturers were appointed for the current year, and the

Digitized by Google

chancellor had stated that neither the sum of £500 nor any other sum was expressly granted for the purpose. This relinquishment by the council of control over clinical teaching elicited a protest from the Faculty of Medicine, and left the students without systematic training, and only such instruction as they could gather during the ordinary visits of the medical staff at the Melbourne Hospital. It was felt that when this became known in Great Britain, the recognition hitherto accorded to their courses of instruction would be discontinued, and already evidence had been received of this from London and Edinburgh, where instances had occurred of the inability of students to obtain certificates of attendance on clinical lectures on surgery and medicine, although they had attended hospital practice &c. in the Melbourne School. While one-half the fees received by the University from students were paid to the Medical School, only one-ninth of the Government grant was devoted to the purposes of that school. Messrs. Goodall and Ick, M.A., and Prof. Pearson also advocated the claims of the students, and Mr. Gillies promised to communicate with the council, and had no doubt the difficulty would be easily overcome. By this time, we trust, the matter has been arranged. It is incredible that a University like that of Melbourne should be without professors of clinical medicine and surgery, not to speak of the hardship inflicted upon the students who, desiring to qualify in Great Britain, find that their course of study at Melbourne has been incomplete.

THE KASHMIR MISSION HOSPITAL.

SINCE the erection of the Mission Hospital in Kashmir in 1875, a large amount of medical and surgical work has been carried on there by the medical missionaries successively in charge of it—Drs. Maxwell, Downes, and Neve; indeed a good deal of what may be called original work and observation has been done, as the various papers which have appeared in our columns from time to time will show. The report for last year has just reached us, and testifies to much suffering relieved by highly scientific methods, Dr. Neve's aspirations being of a commendably high order, for "no surgeon," he says, "is doing his duty who aims at anything less than the best possible result for each individual case." Most of the in-patients, of whom there were 641, were surgical cases. Of 1010 operations that have been performed, 351 rank as major according to the Indian Government classification. The mortality from operations was certainly low, there being only five deaths in all—four from shock, one from tetanus. Dr. Neve considers the practice of antiseptic surgery emphatically economical, as well in diet as in trouble of dressing, to say nothing of its power of saving life and limb.

TRICOCEPHALUS DISPAR AND BERI-BERI.

DR. H. ERNI, of Batavia, writes (*Berlin Klin. Woch.*, No. 37) in support of a doctrine that beri-beri is a secondary anæmia due to the loss of blood produced by such intestinal parasites as ankylostomum duodenale, tricocephalus dispar, and a peculiar dipterous larva. Perhaps the chief interest of his communication is in reference to the tricocephalus, which was far more frequently found in the intestines of subjects of beri-beri than any other parasite; but one or other of the above was rarely present in more than fifty cases examined, whilst they were rarely found in other diseases. Of course, those who contend that beri-beri is an epidemic poly-neuritis, from the evidence of peripheral nerve degeneration, would be disinclined to attribute any share to the presence of such parasites; but similar degeneration to that of the nerves attacks the muscles and other tissues, and may well be ascribed to the chronic anæmia which is the leading symptom. The tricocephalus inhabits the cæcum, and may occur in large numbers. In the slighter cases there is localised inflammation of the cæcum and neighbouring parts of the colon; in others there are definite erosions and points of hæmorrhage which have been produced by the worm; whilst in others, again, the mucous membrane is even undermined by the parasite. Hence the cases are characterised more or less by intense symptoms of enteritis. The obvious criticism upon the thesis of Dr. Erni is that the tricocephalus is a very common parasite in Europe (in Paris it has been stated that one-half the population is infested by it), and that it has never been hitherto assigned so serious a *rôle* as that which he awards it; unlike the ankylostomum, which has been fully proved to be the cause of fatal anæmia as exhibited in the St. Gothard miners and in Egyptian chlorosis. It is hardly conceivable that a parasite which is harmless in Europe should be capable of producing such grave intestinal lesions in the East Indies; for although under the term "beri-beri" doubtless many varieties of purely secondary anæmia may be included—comprising, we are willing to believe, cases of "ankylostomiasis,"—yet more evidence must be forthcoming before the tricocephalus is accepted as a prime etiological agent in the affection.

PUBLIC HEALTH IN PENNSYLVANIA.

THE State Board of Health have submitted to the various cities and boroughs within their jurisdiction a model ordinance for the better preservation of public health, together with a recommendation that its provisions should be adopted with such modifications or additions as may be found needful in special localities. The plan adopted is much the same as that which has been followed by such excellent results from the issue by the Local Government Board in this country of its series of model bye-laws dealing with sixteen separate subjects. Whilst, however, our own codes are much more detailed and comprehensive than that issued in Pennsylvania, the latter deals with some subjects which in this country are dealt with by special statute. Thus, facilities being given for gratuitous vaccination, a section is inserted to the effect that "no pupil shall be allowed to attend the public schools ..... who has not been vaccinated successfully within seven years." In this, and in similar ways, vaccination, which is made directly compulsory in this country, becomes indirectly so in several of the American States.

CHOLERA INTELLIGENCE.

THE cholera intelligence for the fortnight ending Sept. 14th involves several points of importance. In the first place, whilst there has been no general increase in the amount of cholera in Italy, yet the disease has shown itself in several newly invaded places with considerable virulence. Thus, at San Marco in Lamis, there have been 109 more deaths, and at Torre del Annunciata 83 deaths have taken place; the outbreak in this latter place being the most prominent feature of the extension of the epidemic to the Bay of Naples, where Castelamare has also been fatally affected. Five cases have also occurred in Naples itself, but it is believed that these have all been immigrants from other affected localities. Putignano and Taranto are two other freshly invaded districts in Southern Italy, 68 and 8 deaths respectively having occurred in these places during the period in question. The disease also clings with considerable tenacity to several of the towns and provinces in the north-east of the kingdom. From Sept. 1st to the 14th there were 59 deaths in Ravenna, 26 at Padua, and 65 at Ferrara. In all, the records published for the fortnight give 528 fatal attacks in Italy, and this although, as regards several places, there are blanks in the returns which make them very incomplete.

Digitized by Google

It has also been announced that cholera during the present year has attacked 45,000 persons in Italy, and that of these 14,000 have died. For several days there have been rumours of an increase of cholera in the neighbourhood of Trieste, and of the extension of the disease to Pesth, and it is now announced that on the 12th inst. twenty cases and eight deaths occurred from cholera in the latter city. The disease is also stated to be rapidly spreading in Croatia, where isolated cases have for some time past occurred. Perhaps the most important consideration involved in this news from the Austro-Hungarian Empire lies in the fact that cholera is invading entirely new territory. This must materially affect the prospects for next year. It had been hoped that the disease, especially as seen in North-eastern Italy, indicated the termination of the epidemic of 1884-86, but this fresh extension may perhaps come to be the first sign of a probable prolongation of the visitation into 1887. From this point of view cholera in Hungary has especial interest.

MECHANICAL REMOVAL OF CROUPOUS EXUDATION AFTER TRACHEOTOMY.

AFTER tracheotomy for croup, when it is found impossible to clear the trachea from membrane by forced expirations, suction, &c., Dr. Pievigzèk, writing in the *Przeglad Lekarski*, advises the use of Schrötter's forceps, which, he says, should be so introduced through the wound that the blades may open antero-posteriorly, and not laterally, for fear of taking up the angle at the bifurcation of the bronchi. Sometimes it is possible completely to clear the trachea by one or two introductions of the forceps. In cases where the obstruction is in one of the bronchi, the patient should be laid on the corresponding side and the forceps inclined accordingly. Information may also be obtained as to the situation of the obstruction by the aid of a mirror introduced into the wound, the patient's head being at the same time thrown well back. The instrument which the author finds most suitable for this purpose is Zanfal's nasal speculum. He remarks that children bear the operation without any special trouble.

AN UNOFFICIAL PHARMACOPŒIA.

AT the meeting of the British Pharmaceutical Conference held at Birmingham last week, the President, Mr. Thomas Greenish, in his inaugural address, referred at some length to the present unsatisfactory condition of the art of pharmacy. He stated that the British Pharmacopœia in no way represented the advance which had been made in their department of science in the long interval which had elapsed between its publication and the preceding issue. It was simply a collection of fragmentary papers, with an absence of the applied practical knowledge necessary for the proper elaboration of such a work. The result had been most unfortunate, and, excepting in some of the large centres and more important provincial towns, pharmacy had no existence for pharmacists, the whole of the work being absorbed by medical men, to the detriment of the interests of those whose legitimate calling it was supposed to be. Prescriptions were now so rare that, when one made its appearance once a fortnight or thereabouts, there was quite an excitement to see the curious interruption to their ordinary duties. There was a growing evil which might be called "wholesale prescribing for the medical profession." Proprietary preparations, for the most part "factory made," were thrust upon doctors and unblushingly advertised, sapping the foundations of pharmacy and depriving the pharmacist of the legitimate practice of his calling. Chemists were harassed by the demand for these proprietary medicines, which prescribers took up without thought, and without a second thought thrust aside. It should be the business of the Conference, as soon as unofficial preparations of a certain type attained favour with the profession, to construct formulæ fairly representing them, and issue them as unofficial formulæ, which might be prescribed by medical men with the addition of the letters "B.P.C.," or British Pharmaceutical Conference. At the conclusion of the address, it was resolved—"That in order to secure greater uniformity of composition and strength in non-official remedies, and also to enable the medical profession to prescribe them with definite knowledge of those qualities and without indicating any particular maker, the British Pharmaceutical Conference undertakes the preparation of a formulary of non-official remedies." With the view of giving the resolution effect, a committee was appointed with instructions to enter on its labours at once, a grant of money being placed at its disposal for expenses. The *Chemist and Druggist*, commenting on the President's address, points out that an article is not necessarily bad because it is "factory made," and that there is no special reason why proprietors of such articles should be expected to blush when they advertise them. True pharmacy is not a religion hedged about by dogmas never to be changed or challenged without calling forth a charge of impiety, but simply a business free to all with certain qualifications, and requiring vigour and intelligence for its successful prosecution. The doctors who first ordered small bottles of concentrated medicines—"ten drops to be taken in a wineglassful of water"—did a great deal towards sapping the foundations of the true pharmacy of fifty years ago, but chemists and druggists had to adapt themselves to the change.

HYDROPHOBIA.

OUR Paris correspondent writes:—"The following case of authenticated cure of hydrophobia addressed to Dr. de Pietra Santa, and which was published in the *Journal d'Hygiene*, may be of interest. A peasant of Saint Anastasia, near Naples, aged fifty-two, was bitten on the 10th of May last in the leg and in the forearm by a dog whose rabid condition was verified at the necropsy. On July 28th the man was suddenly seized with malaise, excitement, and oppressed breathing, accompanied with a sense of constriction in the throat. His wife offered him a glass of water, but the sight of this liquid immediately threw him into a fit of mania, which was followed by convulsions. He was taken to the Hospital for Incurables at Naples, where he was admitted into the ward of Dr. de Capua in a most deplorable condition. The patient complained of feeling cold; the sight of water and the slightest current of air provoked a great degree of excitement, convulsions, and delirium. Basing his faith on the eminently parasiticidal virtue of corrosive sublimate, Dr. de Capua immediately practised repeated injections of this salt subcutaneously, and combated at the same time the nervous paroxysms (culminating symptoms of rabies) with injections of atropine, which he alternated with those of the corrosive sublimate. The injections were renewed the following days. This treatment was crowned with full success. The rabic symptoms amended progressively, and after a few days the patient was able to swallow a glass of water without wincing. Soon after this he asked to eat and drink, and expressed a desire to leave the hospital. Dr. de Capua observes that the delirium in this case assumed three distinct forms, which followed one after the other. In the first place it was mournful and melancholic; the patient believed himself to be the object of all kinds of persecution. This was succeeded by a delirium bearing a relation to his profession: he imagined that he was occupied at his village with his usual agricultural pursuits.

Digitized by Google

Then came the mystic form, manifesting itself by prayers and religious hymns from morning till night. Dr. Macario, of Nice, the author of this paper, concludes it with the recommendation that physicians and physiologists should undertake experiments, either to confirm or disprove the therapeutic value of corrosive sublimate and of atropine against rabies, adding that if clinical observation and experimental tests on animals confirm the efficacy of the medication proposed by the Neapolitan physician, we shall have at our disposal two powerful arms to combat the most terrible of maladies—the anti-rabic inoculations of Pasteur as a prophylactic means, and the subcutaneous injections of corrosive sublimate and atropine of Dr. de Capua as a curative measure. This will be one of the most marvellous conquests of modern medical science."

SCARLATINA.

THE *Birmingham Medical Review* contains a contribution to the pathological anatomy and histology of scarlatina by Dr. Crooke. It is remarkable that the mammilated appearance of the pyloric region of the stomach was very marked in a case that terminated fatally in twenty-six hours. Microscopical examination showed that this appearance was due to inflammatory hyperplasia of the adenoid tissue, which is normally present in the gastric mucous membrane of children and young adults, as Dr. Herbert Watney has demonstrated. At some places the hyperplasia is seen to be so considerable as to extend up to the surface of the mucous membrane, displacing in its extension the gastric tubules. Whilst able to corroborate the accuracy of the observations of Dr. S. Fenwick as to the presence of interstitial gastritis in scarlatina, Dr. Crooke does not regard the interstitial change as evidence of a past morbid process. He believes that simple catarrhal gastritis occurs in a more or less marked degree in most cases of scarlatina, fatal during the febrile stage; but that in cases characterised by the exceptional severity of the gastric disturbance, where the interstitial changes are so pronounced as in three cases examined by him, the condition is usually, if not invariably associated with a similar acute interstitial and follicular inflammation of the mucous membrane of the intestine, and is therefore to be regarded as part of an acute inflammatory attack, of which the chief stress falls on the adenoid tissue of the stomach and intestines.

THE ROYAL BELGIAN SOCIETY OF PUBLIC MEDICINE.

THE Belgian Society of Public Medicine has just held its annual meeting, which was attended by a large number of persons. M. H. Kuborn presided. The main question discussed was, "the removal of excrementitious matter from towns and thickly inhabited localities unprovided with sewers." In the report, which was adopted after a lengthened discussion, a strong condemnation is expressed of cesspits (*puits perdus*), and an opinion hazarded that they should be forbidden by law. The system of separating solid and liquid sewage is also condemned, as are all the known methods of disinfection, which, it is remarked, are expensive and frequently destructive of the fertilising properties of the sewage. Deodorisation processes are admitted to be valuable in certain cases only, as in camps, hospitals, and isolated barracks or houses. The system of cesspools and movable receptacles (*fosses mobiles*) may be permitted under strict surveillance, but a regular system of sewage acting by gravitation or worked by pumps is much better from a hygienic point of view than any other; this system should be water-tight, and should convey sewage of all kinds to one or more central reservoirs. The question, therefore, which the Society had to discuss seems to have been somewhat shirked, for the reply is virtually, "If there is no system of sewers in existence, the only thing to do is to construct one." It is to be hoped, too, that the omission of all mention of sewer ventilation in the report does not imply that that is considered an unnecessary precaution.

DISEASE OF THE NOSE CAUSING APHONIA AND DYSPNŒA.

DR. PREDBORSKI mentions in the Polish journal *Gazeta Lekarska* a case of aphonia and spasmodic dyspnœa, where the cause was found to be an affection of the nose. A young Jewess, subject from childhood to attacks of epistaxis, received a severe nervous shock, being, in fact, the subject of an attempted violation. After this she completely lost the power of speech and began to suffer from attacks of spasmodic dyspnœa; her catamenia also ceased. One of the attacks was so alarming that it was thought that tracheotomy would have to be performed, and preparations were made for the operation, but, on chloroform being given, her condition improved so much that she not only breathed more easily but began to scream, so that all thought of operative procedures was abandoned. In a few weeks' time the girl seemed much better, but subsequently the symptoms reappeared. The nose, on examination, showed that the lower and middle turbinated bones on the left side were red and tumefied. When they were touched pain was produced, accompanied by sneezing and discharge of mucus. The application of chromic acid quickly and completely restored the patient to her usual state of health.

THE MASSACRE OF THE INNOCENTS.

A CASE of poisoning which serves forcibly to illustrate the necessity for caution in the administration of opiates to children has recently occurred at Goole, and has been the subject of an investigation by Dr. Grabham, the coroner for the Honour of Pontefract. From the evidence of the mother, it appears that her child, aged nine weeks, having been cross all day, she sent the servant girl to the chemist for a pennyworth of Godfrey's cordial, giving her an old bottle labled "Poison" to fetch it in. She noticed a brown coating at the bottom, but did not take the trouble to wash it out. When the girl returned, she took the bottle off the sideboard and gave the baby a teaspoonful. She then found she had made a mistake, and shortly after the child died. The servant stated in evidence that she misunderstood her mistress and asked the chemist for a pennyworth of laudanum. When she came back she was sent out again directly, and put the bottle down on the sideboard, and that was how it happened. The chemist deposed that he did not recollect the last witness coming to his shop, as so many people came for laudanum, and he sold pints of it in the course of the week. The coroner, in summing up, said the cause of death was clear. The mother admitted that she had given the child a teaspoonful out of the bottle, whilst the servant told them that she had asked for laudanum instead of Godfrey's cordial. He did not blame her, for she was young and thoughtless, and had only been entrusted with a verbal message to get a pennyworth of the cordial, which she had translated into laudanum on her way to the shop. Even if she had not made the mistake, there was probably enough dried laudanum at the bottom of the bottle to have caused the child's death. He could not blame the chemist, for he was within the law in selling laudanum without asking what it was for, the Act of Parliament simply requiring that a poison label should be placed on the bottle. It was startling to be told by the witness that every week he sold pints of laudanum to his customers, for it could not be supposed

Digitized by Google

that even a fraction of this was required for external application. The existing law regulating the sale of poisons was to blame, and he trusted the Government would soon take steps to remove this blot from the statute-book. Steps should be taken to protect both infant and adult life, for the number of people killed every year by opium, whether sold as such or in the form of quack nostrums, was frightful to contemplate. Opium in any form was a dangerous poison to young children, and should never be administered to them without the advice or under the superintendence of a medical man. The jury returned a verdict of "Death by misadventure." At an inquest held a few days ago at Kensal-green, Dr. Diplock, the coroner, told the jurymen that they "would be astonished if they knew the number of deaths through parents taking their children to chemists, and thus losing time in the proper treatment of disease." The necessity for legislation in the direction of the better protection of infant life is apparent.

INTESTINAL LESIONS DUE TO CORROSIVE SUBLIMATE.

THE use of the corrosive sublimate in general antiseptic surgery has led MM. Charrin and G. H. Roger to investigate the intestinal conditions said to be caused by the absorption of the salts of mercury. Although there can be no doubt of the capacity of mercurial salts absorbed into the blood to produce serious changes in the intestines, yet it has been questioned whether the solutions ordinarily employed are capable of causing the intestinal lesions which have been attributed to their action. It must always be remembered that in the cases in question the chance that the intestinal lesion may have been caused by the disease from which the patient is suffering always exists. The experimenters above mentioned have injected under the skin and into the veins of rabbits and guinea-pigs a solution of 1 in 1000 and 1 in 4000 of corrosive sublimate. Administration by the mouth has not been practised, because Prevost has shown that quantities ten times as large as those injected hypodermically would be required to produce the same effects. It has been found that a medium dose injected at a single time had more effect than a much larger dose administered over a longer period. Thus, to a guinea-pig weighing 500 grammes, two milligrammes injected at once under the skin may determine the formation of numerous ulcers, whilst five milligrammes given in eighteen days, or three in six days, produced no effect. The animals experimented upon have rarely shown special indications of intestinal lesions; emaciation and albuminuria frequently occurred, but rarely diarrhœa, and never intestinal hæmorrhage. Small doses only being administered, the animals have never died, but have been killed at different periods in order to follow the evolution of the intestinal changes. The lesions have always been confined to the large intestine, and chiefly to the ascending colon and cæcum. In some cases the ileo-cæcal valve was attacked, and occasionally the lower part of the ileum. The essential nature of the changes appears to be a hæmorrhage, which first of all takes the form of minute points; these gradually increase in size until areas of extravasated blood are formed, which may undergo a kind of sloughing, the varying degrees of extravasation being in direct proportion to the amount of the poisoning. Inflammation may take place around the extravasations, but perforation has never been observed. To transfer these facts to the domain of human pathology, it would appear that a single dose of ·24 gramme (or ·60 gramme spread over five days) would be required in order to produce the intestinal lesions always assuming, what we have but little right to do without actual observations to support the supposition, that the susceptibility of men to the poison is the same as that of the animals experimented upon. It is not impossible that the intestinal lesions in man may be induced by very small doses of the sublimate.

COLD BATHING.

THE use of cold water as a bath for ordinary health purposes—we are not speaking of its use for the strictly medical purpose of reducing the temperature of the body in certain states of disease—is purely reactionary. The cold bath is only useful, or even safe, when it produces a rapid return of the blood to the surface immediately after the first impression made, whether by immersion or affusion. The surface must quickly redden, and there must be a glow of heat. If these effects are not rapidly apparent, cold bathing is bad; and no such effects are likely to be produced unless the circulation be vigorous and both the heart and bloodvessels are healthy. Great mistakes are made, and serious risks are often incurred, by the unintelligent use of the cold bath by the weakly or unsound. Moreover, it is necessary to bear in mind that there is seldom too much energy to spare after middle age, and it is seldom expedient for persons much over forty to risk cold bathing. We would go so far as to say that no one above that age should use the tub quite cold unless under medical advice. It is possible to be apparently robust and, for all the average purposes of life, healthy, and yet to have such disabilities arising out of organic disease or weakness as to render the recourse to heroic measures, even in the matter of cold bathing, perilous.

THE SANITARY STATE OF WEST COWES.

BOTH those who assail and those who uphold the existing sanitary circumstances prevailing in West Cowes have taken the opportunity to make known their views in the public press. One side asserts that infectious disease prevails there in connexion with states of sewerage and water-supply that should not exist; and the other side, giving an estimate of their own as to the present population, try to prove a low mortality in the place, and also declare that the sewerage has been carried out according to the wishes of the Local Government Board. Most of the statements on both sides are thus far very general, and all we know for certain is that diphtheria has been prevalent in the place. When Mr. Spear's report is issued, the matters in default will probably be specifically referred to, and then they can more advantageously be discussed.

RESIDENCE IN FLATS.

IN connexion with the subject of house rents, the question of residence in flats is being a good deal discussed and its advantages are being advocated. There is one point to which we would advert as worthy of consideration in settling whether a flat is preferable to an entire house. Flats have generally the advantage of being of modern construction, and it may in many cases be inferred that some of the principal evils due to faulty and defective drainage in old houses are avoided in them. But, on the other hand, cases have come to our knowledge in which the drainage of first-class buildings laid out in flats has been found to be seriously defective, and then the tenants find themselves in considerable difficulty, since they are without the control which an ordinary householder has over the general sanitary arrangements of his house. The defect in question is not usually one affecting the drain connexions in the individual flat, but the whole premises suffer from the want of the passage of a constant current of air through the general house drain, such as is secured by the provision of an inlet and outlet pipe on the house side of an efficient trap before

Digitized by Google

the drain reaches the sewer. Some tenants, after constantly suffering from indisposition from inhalation of drain air, have been compelled to give up their flats. It would be well if owners of flats were to secure a certificate from some expert in sanitary engineering, to the effect that the drainage arrangements affecting the entire establishment were carried out on proper principles.

A CONJOINT EXAMINING BOARD FOR IRELAND.

THE scheme for constituting an Examining Board in Ireland by the College of Physicians and the Royal College of Surgeons in Ireland, under the provisions of Section 19 of the Medical Act, 1858, is almost complete, and but slight modifications of the report presented by the committee appointed by each College may be expected. The Examining Board will consist of twenty-four members, twelve being appointed by each College, who will pay the examiners whom they may appoint. The subjects for examination will be chemistry, physics, materia medica, pharmacy, anatomy, physiology, and histology; medicine, surgery, midwifery, and diseases peculiar to women; therapeutics, forensic medicine, and hygiene; pathology; and the Council of the College of Surgeons propose to add ophthalmic and aural surgery. A committee of management will arrange the examinations and perform other duties; and this committee will consist of three representatives from each College, to be elected annually, and to be disqualified from holding the office of examiner. The committee annually elect a secretary, whose remuneration is to be shared equally by the Colleges. No person engaged in private tuition will be eligible for the post of examiner. There will be four examinations, one at the end of each year of professional study, the student being examined in anatomy in three several years; in physiology on two occasions; chemistry the same; and in surgery in the third and fourth year; while the College of Surgeons recommend at the end of the second year of study an examination in hospital practice—elementary, medical, and surgical; and the same body suggest that in the fourth year the subjects should include ophthalmic and aural surgery. There is very little difference in the number of lectures and the hospital attendance usually required up to this for the licence of either College, and the fees are fixed at the same amount—viz., £42, for which sum the licence of both Colleges can be obtained.

THE CLEARING OF DUSTBINS.

A WELL-KNOWN firm have complained in a contemporary of the nuisance caused to themselves and their customers by the collection of house-dust by the scavengers at two o'clock in the afternoon. Mr. John Braye, a member of the Kensington vestry, writes also to the same journal to say that after much inquiry he finds that "a well-organised early morning collection daily is not more expensive than the old and slovenly system of dustbins. The receptacles are provided by the corporation, they are placed outside the dwelling in the morning, and all the men have to do is to tip the contents into their vans." He cites the arrangements of Glasgow, where it is a common practice to have a daily collection of dust, and says that last year Glasgow sent 186,000 tons of dust to fourteen Scotch counties, and sold it to the farmers for manure, realising a profit of £13,700, after paying upwards of £10,000 for railway carriage. There is indeed not the least doubt that the scavenging of the metropolis could be effected in a far better manner than at present. Some slight difficulty would have to be surmounted in effecting an alteration of a method that has been in existence for years. But this is not the chief obstacle. The real hindrance to any improvement is to be found in the fact which Mr. Braye points out, that "to scavenge the high road from Tattersall's to Charing-cross it takes the divided exertions of no less than six vestries and district boards of works, each with a separate system."

THE DRESS OF FEMALE PAUPERS.

SOME good has probably been done by the City of London Board of Guardians in raising a discussion on the dress of female paupers. It is true the Board came to no actual decision, but they opened the question, and it is one which ought to benefit by investigation. While, in the opinion of some, the check fabrics of light material now in use might be discarded in favour of black stuff dresses, which are less suggestive of public charity, others oppose this change on the ground that black stuff will not wash, and must therefore tend to harbour vermin. The objection, we fear, is a valid one in regard to most kinds of black cloth which are available for this purpose. The composition of such goods—a mixture of wool and vegetable fibre,—apart from the too common instability of modern dyes, renders them unsuitable for washing. As a possible solution of the difficulty, we would suggest that a light material be used as heretofore, the dye being varied if desired, while care is taken that the underclothing (which ought to be woollen) is such as to allow of the same dress being worn at all seasons. A double advantage in comfort and improved appearance might thus be gained.

HÉNOCQUE'S HÆMATOSCOPIC METHOD.

M. HÉNOCQUE exhibited to the Medical Congress at Nancy last month his apparatus for investigating the blood by *hæmatoscopy*. The process consists in first determining the amount of oxyhæmoglobin in the blood by the hæmatoscope, and then estimating the time required for its reduction by observing its passage across the thumb-nail through a direct vision spectroscope. The activity of reduction varies independently of the quantity of oxyhæmoglobin, being generally increased in persons of sanguine habit and in patients with arthritic and rheumatic diseases, and diminished in those with anæmia, chlorosis, epilepsy, temporary bilious disturbances, menstrual troubles, and in certain stages of phthisis.

FACTORY INSPECTORS.

THE Secretary of State for the Home Department, in answer to Mr. Reed, intimated that he did not propose to increase the number of inspectors of factories. This will be a disappointment alike to the advocates of working-class interests and of sanitary reform. To mention only one detail, we have frequently demonstrated in these columns how inadequate is the inspection of the "sweaters' dens" that constitute a permanent scandal in the East-end of London. Mr. Lakeman has spent much energy and time in coping with the evil; but the work is altogether beyond the powers of any one inspector. We have further urged that a detective service should be instituted. No one is, perhaps, better known in the East-end of London than Mr. Lakeman. There is a regular signal by which his approach is notified to all the "sweaters." Thus they have ample time to put their houses in order, to conceal or send away the women and children working beyond the regulation hours, or the extra hands that overcrowd the workshop. No one who is in the least degree acquainted with the subject can doubt that for the proper enforcement of the Factory and Sanitary Acts a much larger number of inspectors is absolutely necessary; and these officials should also be able to employ, at least occasionally, a detective force. Mr. Matthews' answer is, consequently,

Digitized by Google

very discouraging for those who anticipated that the present Government would forward those legislative and administrative measures which, though unsensational and unpretentious, very largely contribute to the real welfare of the people.

THE PERONEAL TYPE OF PROGRESSIVE MUSCULAR ATROPHY.

THE thesis prepared by Dr. Howard Tooth for the degree of M.D. in the University of Cambridge contains valuable information and an excellent bibliography. The author of the thesis contends that there is a form of progressive muscular atrophy which commences in the lower extremities, most often in the peroneal muscles, but sometimes in the tibialis anticus, extensor longus digitorum, or gastrocnemius; that the hand and forearm muscles are attacked at an early period; that the disease is one of childhood; that heredity is a marked feature; that the disease shows a slight preference for the male sex; that fibrillar or fascicular tremors are frequently, though not always, present; that degenerative electrical reactions are often an early phenomenon; and, lastly, that from a record of necropsies, as well as from the clinical symptoms, it may be inferred that the disease is one affecting the peripheral nerves.

THE SANITARY CONDITION OF WINDSOR.

ON the 14th inst. Mr. Ritchie, President of the Local Government Board, received a deputation from New Windsor, to protest against the charges made by THE LANCET in respect of the insanitary condition of Windsor, and to ask the Local Government Board to appoint an inspector to investigate the subject. Mr. Ritchie, in reply to this request, said that the matter was one of very great importance to Windsor, and that, looking to the exceptional circumstances of the case, he should feel inclined to grant their request. He assumed that the sanitary authority would remedy any defects that might be pointed out. As it was important that the matter should be attended to quickly, Mr. Ritchie intimated that the inquiry would be instituted in the course of a few days.

"SCOTODINIA."

THE term "scotodinia" is probably not often used by medical men nowadays, but it was mentioned recently in the course of consultation, and its precise meaning not being evident to all the members of the consultation, it may be as well to say that the term is used to signify the not unfrequent combination of symptoms of blindness with giddiness. It does not necessarily refer to Menière's disease, for scotodinia is a symptom of a great variety of pathological states, such as gastric disorders, anæmia, and various forms of toxæmia, whether associated with weakened action of the heart or not.

COCAINOMANIA.

ERLENMEYER, in the *Deutsche Medizinal Zeitung* (1886, No. 46), has studied the symptoms in a number of individuals who have used cocaine to excess, by subcutaneous injection or otherwise. The characteristic symptoms denote vaso-motor paralysis, the pulse is accelerated, the sweats profuse, and dyspnœa and syncope ensue. Failure of general nutrition is very notable, the eyes become sunken, and the skin of cadaveric hue. At a more advanced stage psychic troubles supervene, sometimes requiring personal restraint. Most of the persons so affected had previously been addicted to the abuse of morphia, and cocaine had been resorted to as a minor evil. It would therefore be unjust to lay too large a share of the troubles noted at the door of cocaine; still, enough evidence is at hand to prove that it may be productive of evil consequences, and should only be used as a powerful medicament with circumspection.

CLEANSING THE BLACKWATER.

WE have from time to time directed attention to the insanitary condition of the low-lying marshes between Aldershot and Wellington College Station, through which the stream known as the Blackwater, a tributary of the Thames, runs. This stream has been for years past clogged with mud and filth, partly derived from the marsh-lands, and much contaminated by sewage deposits, which in the past have been allowed to pollute the stream; it is satisfactory to find the several sanitary authorities having jurisdiction over the districts bounded by this stream, are about to act in concert, with a view to clean out the Blackwater, between Aldershot and Sandhurst. The cost of such a work must be considerable; and it appears reasonable that each district should bear its proportion of the cost. The Blackwater stream forms the boundary of several districts, and is the boundary also of the counties of Berks, Hants, and Surrey, where these counties meet in the valley of the Blackwater. Thus, there are not only several sanitary authorities interested in the subject, but the three counties also. This complicates somewhat the estimate of the proportion each district should bear. We hope this will not interfere with a thorough execution of this much-needed sanitary improvement.

THE SURGERY PROFESSORSHIP IN QUEEN'S COLLEGE, BELFAST.

IN addition to the candidates mentioned in THE LANCET of the 7th ult., it is announced that Dr. Thompson, Surgeon to the County Tyrone Infirmary, is in the field. It is expected that the appointment, which is a Government one, will be made shortly.

FOREIGN UNIVERSITY INTELLIGENCE.

Kharkoff.—Dr. N. Saleski, Extraordinary Professor, has been appointed Professor of Pharmacology.

Leipsig.—Dr. Friederich Albin Hoffman, Professor and Director of the Medical Clinic and Polyclinic in Dorpat, has been appointed Professor of Special Pathology and Therapeutics and Director of the Medical Polyclinic.

Prague (German University).—The Professorship of Midwifery and Gynæcology, vacated by Prof. Breisky, who has gone to Vienna, has been filled by the appointment of Dr. Ludwig Bandl, Extraordinary Professor in Vienna.

Odessa.—Dr. M. Rasumovski has been appointed to lecture on Medical Jurisprudence in the Legal Faculty.

WE regret to learn that Mr. T. M. Stone, so well known to the profession through his services during nearly half a century at the College of Surgeons, when returning from the funeral of the late Dr. Wakley, was seized with a fit or faint, and fell on his face. He was found by a passer-by, bleeding much from his face, and taken to a farmhouse, where he received attention and assistance. He was seen on the following Monday by Mr. Henry Smith, who found he had received a severe wound on his nose and contusion of the face. Mr. Stone, we are glad to say, is now so far well as to be able to drive out.

THE Cama Obstetric Hospital at Bombay, the foundation stone of which was laid in 1883 by H.R.H. the Duke of Connaught, was formally opened on July 30th by her Excellency Lady Reay, the lady president of the Western India Branch of the Association of India for the supply of Female Medical Aid.

MR. WALKER of Newcastle, the public analyst for Carlisle, has announced, as the result of a microscopic examination of the ham forwarded to him by Dr. Henry Barnes, and which was suspected as the cause of the recent poisoning of a Carlisle wedding party, the discovery on several occasions of a bacillus which he is now cultivating in different media. This discovery, it is thought, may lead to a satisfactory elucidation of the mystery which so long surrounded the case. Dr. Page of the Local Government Board has been instructed to assist in the inquiry. Portions of the ham have also been sent to Mr. Watson Cheyne and to Professor Greenfield for examination. We hope to be able to give, probably next week, a detailed history of this interesting case.

SCARLET FEVER, which has existed for several months in the Cumberworth district of the Huddersfield Union, is reported to be greatly on the increase. The district includes the parishes of Cumberworth, Denby Dale, Shelley, and Skelmanthorpe. We are informed on good authority that one practitioner alone has had sixty-one cases brought under his notice.

THE address delivered by Mr. Erichsen in the Surgical Section of the British Medical Association at Brighton has been translated into Spanish by Dr. Ulecia of Madrid, and appears in the current number of the *Revista di Medicina y Cirurgia Practical*, and into Italian by Dr. Longhi of Milan, for the *Gazzetta degli Ospitali*.

THE managers of the Hudson River State Hospital, Poughkeepsie, N.Y., have established, in connexion with the institution under their charge, a training school for the instruction of those who wish to make a specialty of nursing the insane, either in private houses or public institutions.

DR. PEKELHARING, Professor of Medicine in the University of Utrecht, has been instructed by the Government at the Hague to proceed to Acheen to make special inquiry into the nature of the malady known as "beri-beri."

THE proposed special grant to the Belfast Royal Hospital is threatened with strong opposition by Mr. T. W. Russell, who has been promised the support of Mr. Labouchere and several other leading Radicals.

THE nineteenth annual meeting of the Canadian Medical Association was commenced at Quebec on the 18th ult.

THE PRIVY COUNCIL AND THE APPROACHING ELECTION OF DIRECT REPRESENTATIVES.

OUR readers will remember that the Medical Act of 1886 left the making of regulations for guiding the procedure of the Branch Councils in the matter of the election of direct representatives with the Lords of the Privy Council. The *London Gazette* of Sept. 3rd contains the orders and regulations of their lordships. A schedule contains the regulations, and an appendix gives certain forms. Form A is a notice of the election, to be published at least fourteen days before the election in at least two newspapers in the part of the kingdom in which the election is to be held. Form B is the precept of the returning officer, the President of the Medical Council requiring the Branch Council of each division to cause the election of the proper number of representatives. Form C is a form of Nomination paper. Form D is the form of Voting paper, to be prepared and forwarded in due time by the Branch Council of each division to each registered practitioner in that part of the United Kingdom. As the nomination of candidates is the act of the profession, and those nominating are required to keep as nearly as possible to the prescribed form, we append Form C. The other forms are for the guidance of the returning officer or the Branch Councils.

FORM C. (*Form of Nomination Paper.*)

We the undersigned, being registered medical practitioners resident in* , hereby nominate† of‡ a registered medical practitioner, as a proper person to be elected to the General Council of Medical Education and Registration of the United Kingdom by the registered medical practitioners resident in*

(Date) Signed§

* Here insert England, Scotland, or Ireland, as the case may be.
† Here insert name of person nominated, in full.
‡ Here insert address and registered qualification or qualifications of person nominated.
§ To be signed by not fewer than twelve registered medical practitioners, to the signature of each one of whom his address and registered qualification or qualifications must be appended.

The regulations themselves have interest chiefly for the Returning Officer and the Branch Council. But one or two points of interest may be noted. As to the time of the election, the exact date still rests with the returning officer. But their lordships "order and direct" that for the purposes of the next election of direct representatives the returning officer shall, in the course of the period of seven days ending with the 13th November next, *issue his precept to the Branch Council* in each part of the United Kingdom, as required by the eighth section of the Act. Now this said section requires the Branch Council to cause the representatives to be elected within twenty-one days after the receipt of the said precept. This would involve the selection taking place on or before the 4th of December. The last day for sending in the *nomination* papers is to be fixed by the returning officer, and at least fourteen days before the day so fixed the returning officer is to cause a notice of the election to be published specifying the number of persons to be elected, the place where the nomination papers are to be sent in, and the last day on which they are to be sent. This notice is to be published in at least two newspapers. But doubtless the returning officer will publish it in the medical papers for greater certainty of its being seen by nominators of candidates. As to the voting papers, they will be prepared and forwarded by the Branch Council. These papers will contain a list of the candidates, and the voter is to write his initials in the space against the name of the person or persons for whom he intends to vote. Those interested in the election of candidates will do well to supply themselves with a copy of the *London Gazette* of September 3rd.

THE NEW SYDENHAM SOCIETY.

THE twenty-eighth annual meeting of the New Sydenham Society was held in the Pavilion at Brighton, August 13th, Mr. S. W. Sibley in the chair.

The minutes of the last meeting were read and confirmed.

The Secretary read the draft of the report as prepared by the council, and the statement of the Society's income and expenditure; the balance-sheet for 1885 had been duly audited by Dr. Clapton and Mr. Corner, by which it was shown that the receipts amounted to £2092 5*s.* 4*d.* and the expenditure to £2174 2*s.* 2*d.* It was moved by Dr. Moore, of Dublin, and seconded by Mr. Jessop, of Leeds, "That the report and balance-sheet, as presented by the council, be adopted, and, as usual, printed for circulation." For the present, it is intended to restrict the Society's work chiefly to translations of modern books. The work adopted for translation during the year is a series of clinical lectures by Prof. Charcot, now in course of publication.

A ballot of the officers for the ensuing year was next taken, when Sir Spencer Wells was elected president, Dr. Sedgwick Saunders was re-elected treasurer, and Mr. Jonathan Hutchinson, hon. secretary.

The following resolution, moved by Dr. Chadwick, and seconded by Mr. Vincent Jackson, of Wolverhampton, "That the best thanks of the Society be given to the retiring officers for their services during the past year," was carried unanimously. It was moved by Mr. Jones Morris, of Portmadoc, seconded by Mr. Jessop, of Leeds, and carried unanimously, "That the best thanks of the Society be given to the honorary local secretaries, on whose exertions in the past so much of the success of the Society depended.' After a vote of thanks to the Chairman the meeting separated.

THE LATE JAMES G. WAKLEY, M.D.

WE might fill several pages of our present number with grateful tributes to the work and character of the late Dr. Wakley, Editor of THE LANCET. It is very gratifying to those concerned in this Journal to receive such communications, and very painful to them to be unable to publish more than a few of them. Those whose communications do not appear will understand the extreme pressure on our space, and will believe that, even out of deference to him whose loss is so acutely felt, we must use it so as to advance the great ends of Medicine. The following lines are from one whose friendship Dr. Wakley valued much. Their authorship might have been guessed without the appended name, which many English readers will, however, be glad to see, as of one still bound by strong ties to this Journal.

IN MEMORIAM—J. G. W.

Non secus ac flerunt Palinurum Troes ademptum
Per freta nocturnam nave tenente viam,
Deflendus nobis raptus de puppe magister
Pervigil adversas tot superare vices:

Digne, mari rerum, qui molireris habenas
A patre donatas deficiente manu,
Direxti cursum, medica ducente Minerva,
Quo genus humanum cunque petebat opem.

Ergo perpetuus carum sopor urget amicum
Quem Pudor et lugent cum Probitate Fides?
Cui fuit in terris curae praestare salutem
Illum habet in caelis non peritura Salus.

J. P. STEELE, M.D.

IDEM ANGLICE REDDITUM.

As wept the Trojans wandering o'er the deep
Their missing Palinure's directing power,
We mourn our Palinurus, prompt to keep
Unerring watch through many a fateful hour:

Oh worthy, on life's waters, of the helm
Thy sire bequeath'd thee! In thy yearly course
Thou hail'dst each harbour of the healing realm
Whence Science still could perfect her resource.

Sound is thy slumber; yet, from o'er thy grave,
Unselfish Worth and Faith, in accents soft,
Say: He whose part below was life to save
Shall rise, redeem'd, to better life aloft. J. P. S.

From medical officers of the Royal Navy letters of condolence have been received, expressive of their sense of their "loss of a sturdy friend and advocate of the rights of their department—one who, during thirty years, never failed to render his aid on every just occasion, by bringing their wrongs and claims to the knowledge of the profession at large, by opening his columns to the communications sent to him by the trusted representatives of the corps."

"THE LANCET" AND THE LATE DR. WAKLEY.

To the Editor of THE LANCET.

SIR,—In one of his essays Bacon says that "they are happy men whose natures sort with their vocations." After reading the articles which have appeared concerning the late Dr. Wakley, I have come to the conclusion that his life was singularly happy. His nature seems to have sorted with his essentially responsible vocation of Editor of THE LANCET in a fashion that is seldom observed amid the feverish changefulness of these latter days. It was indeed fortunate that such was the case, more especially when one remembers and considers the great and, in my opinion, beneficent influence which THE LANCET possessed, and continues to possess, over the words and actions of the medical profession. Under the guidance of Dr. Wakley, it became something more and better than a merely Medical Journal. It has discovered to the profession, and continues to enforce the discovery upon the attention of medical practitioners, the fact that the science of medicine has a higher end before it than is to be found in the every-day work of patching up decrepit humanity. Beyond the usually understood routine of general medical practice there are many questions of moment, with the settlement of which the medical practitioner is concerned. I have always regarded the prevention of disease as the most important part of my duty as a medical practitioner, and I am glad to say that the education of the people in the first principles of sanitary science is becoming the fashion. The necessity for watchfulness in the education of children has frequently been insisted on by the late Editor of THE LANCET. The recognition of insanity in connexion with criminal outbreaks, and the consequently intelligent restriction of the insane criminal; the intimate, and, as I believe, inseparable connexion between physical and mental life; the improvement of the race by means of patient investigation into the wide and far-reaching subject of hereditary transmission of physical virtues and defects; the supply of rational and informing amusements to the multitudes whose thoughts are in their eyes and ears,—with all these, and other questions the medical practitioner is concerned, and it will not be the fault of THE LANCET—if a continuity of its excellent purpose be preserved—if he remain hard and fast in a narrow and thought-obliterating groove.

I have been impelled to write these words by a consideration of the manner in which Dr. Wakley discharged the onerous duties of Editor. For editors in general I have a profound and occasionally panic-stricken respect. They are, in the best and most real sense of the term, absolute monarchs. Dr. Wakley seems to have been a genial and kindly occupant of the editorial throne. For a long period of time, he conducted, with marked and increasing success, a Journal to the words of which, not only a profession singularly jealous of any infringement of its rights, but also the intelligent public, turn an interested ear. He seems to have possessed in full measure a store of that discerning and discriminating wit which, with keen vision, separates the gold from the dross of human life, and without which learning is an unfruitful field; and yet such men as he pass from the knowledge of their kind with little ceremony. A statesman, a soldier, a man of science, or a leader in literature must die in a rude gothic fashion, on the uncurtained stage of life; but the journalist—the interpreter of the world's incoherent babble—dies after the more decorous fashion of the great dramatist, out of the sight of men. The busy world is astonished for the moment when it learns that the editor of this or that important journal is dead. He had laboured with hearty devotion to the cause in which he was engaged, but his labour had been in secret, or known only to the few who had laboured by his side. The influence, however, that such a man exerts on the course of human life and the character of human action remains as an indefinite and immortal essence, and I am Positivist enough to believe that for the honest and conscientious journalist there is an impersonal immortality of the sweetest and most unselfish kind. I do not know if the breathless world will pause for a moment's reflection upon the worth of such a man as Dr. Wakley, or bewilder itself over the consideration of monument and memorial. To his friends, with whom there is not only the sadness of the recent sorrow, but also the satisfaction of reflecting upon his character and worth, the best monument will be the fragrant memory of his well-spent life.

I am, Sir, yours truly,

Glasgow, Sept. 5th, 1886. ROBERT MACPHERSON.

ARMY MEDICAL DEPARTMENT.

IN the discussion which took place in the House of Commons, in Committee of Supply on the Army Estimates, the condition of the Medical Department, and the grievances, especially of the junior officers, were pretty fully discussed. Colonel Duncan, who spoke with a practical knowledge of the working of the service, appears to regret the substitution of the departmental for the regimental system, as he believed the men were better looked after under the latter, "and the medical officer was emphatically a friend among the other officers." But he admitted that the regimental system could not be worked on active service, and that it was necessary to have the same system in peace as in war. A study of the working of the department in our recent campaigns, compared with that of the later years of the regimental system, most fully confirms this opinion. Colonel Duncan bore valuable testimony to the good service done by the medical officers, and to the courage they had shown in the midst of epidemics and in the field. He brought forward, on their behalf, two distinct grievances: the first being the disproportionate amount of foreign to home service; and the second, the examination of surgeons-major previously to selection for promotion. The first of these has, no doubt, pressed hardly upon medical officers during the past few years, but it has been a result of unforeseen circumstances connected with active war, and from the statement of the Secretary of State for War it appears now to be gradually abating. The other point—that of the examination of surgeons-major—is one of great importance, and on it we cannot agree with the gallant Colonel. The evils of promotion to the administrative ranks by seniority, without reference to the special qualities required, were so clearly shown under the old system, that the Commission presided over by Lord Herbert urged promotion by selection as one of the imperative necessities towards the formation of an efficient service. But if a selection is to be made, it is surely necessary that the Director-General should have the means of ascertaining whether the officers to be selected have a competent knowledge of the details of the service which they are to be called upon to administer, and we cannot see how this can be ascertained satisfactorily in any other way than by examination. It was stated as a grievance by several members that medical officers were not afforded an opportunity of "attending London or other hospitals in order to qualify themselves to pass their examinations." But they appear to have overlooked the fact that the subjects of examination are all connected with the administrative duties of the army, and that neither in London nor elsewhere are any lectures delivered which could be of the slightest use for this purpose. It might be a question for the War Office to consider whether a special course of instruction could not be instituted at Netley—a sort of medical staff college; but we fear there would be great practical difficulties. If a surgeon-major cannot in the course of his service acquire a sufficient amount of knowledge of departmental organisation and duties to enable him to pass the requisite examination, we should be disposed to consider it evidence of his unfitness for selection to the higher grades. Colonel Duncan offered a practical suggestion which seems worthy of consideration—"that it would be better if at the large military stations a field hospital were kept constantly standing and fully organised, so that all those in charge of it may be fully trained." Such a course would merely be in accord with the acknowledged necessity for having the same system in peace as in war. We observe with much regret that Dr. Tanner did not follow the example of Colonel Duncan and sum up temperately what are considered the real grievances of the department, but made statements which might have been applicable to the service in former times, but are certainly not so now. He alleged that "the army only got medical officers who were more or less the ruck and scum of the schools, and consequently the soldiers did not get that care and attention to which they were entitled in time of peace; and in time of war the state of things was still more deplorable." When this statement was indignantly repudiated by the Secretary of State for War, it was modified by Dr. Tanner as being applicable to the past, but not actually to the present time. We regret that a member of our profession should have made so loose and inaccurate a statement reflecting discredit upon the medical officers of the army. Complaint was also made by him that the "army medical officers were being constantly sent about from one station to another without having adequate notice given them, which he contended was a great hardship to them, and detrimental to the efficiency of the service." And again he repeated his complaint "that junior medical officers were constantly being sent about the country and not allowed to remain in one district." We hardly suppose the honourable member means that they are sent about in this way for the amusement of the Director-General, or that they should be spared the hardship and the seniors be sent on such duty in their stead. We observe, with satisfaction, that Mr. W. H. Smith spoke in high terms of the "many excellent medical officers to whom the British soldier owed a deep debt of gratitude," and that he has promised to give consideration to the various points raised during the debate, and to improve the condition of the medical officer so far as possible consistently with the interests of the tax-payer.

In reliance upon the expressed intentions of the right hon. gentleman, we would bring to his notice two grievances which appear to us to call imperatively for redress, and which would involve little or no expense. The first regards the gazetting of "surgeons on probation" to commissions. It appears that the commissions of those for the Indian Medical Service are dated from the period of joining at Netley, while those for the Army Medical Department bear the date on which the course of instruction there closes. The practical result of this difference is, that the Indian medical officers become the seniors of the others by four months, and this seniority must continue throughout their career, at least till they reach the administrative ranks. This is so obviously unjust that we feel it should only be necessary to bring it to the notice of the Secretary of State for War to have it remedied. Unless this is done, the difference of treatment cannot fail to act most injuriously upon the supply of candidates for the Army Medical Department. Formerly the rule of dating from the period of joining at Netley applied to both services, but the change was effected by the Warrant of 1877, for reasons which have never been explained. The other grievance is that while honours are conferred upon medical officers for service in the field, no notice is taken of their professional services, often rendered under circumstances of great difficulty and more personal danger, in the treatment of severe epidemics. The duties of the medical officers in saving life by these measures which tend to prevent disease, and their care and exertions in the treatment of the sick, more especially during the ravages of epidemics, are at least as commendable and as valuable to the army as their surgical work in the field; but under the present routine they are systematically ignored. We recommend this subject to the serious consideration of the Secretary of State, in the hope that he may find means to remedy the grievance without affecting the interests of the taxpayer.

THE DIRECT REPRESENTATION ON THE GENERAL MEDICAL COUNCIL.

A MEETING of the General Committee, which has been formed to consider the selection of candidates for the representation on the General Medical Council of the profession according to the provisions of the Medical Amendment Act, was held at the Queen's Hotel, Birmingham, on Tuesday, the 14th inst.

Among those present were: Dr. Saundby (Birmingham), Dr. Waters (Chester), Dr. Roden (Droitwich), Dr. W. Armstrong (Manchester), Dr. Berry (Wigan), Dr. Danford Thomas (London), Dr. Crow (Worcester), Dr. Paul Chapman (Hereford), Dr. Strange (Worcester), Dr. Pike (Malvern), Dr. Lyle (Bromsgrove), Dr. Eyton Jones (Wrexham), Dr. Suckling (Birmingham). Dr. Farrar (Morecombe), Mr. R. H. Nicholson (Hull), Mr. Lawson Tait, Mr. D. Vinrace, Mr. Bennett May, Mr. Jordan Lloyd (Birmingham), Mr. Wheelhouse (Leeds), Mr. Granger (Chester), Mr. Taylor (Chester), Mr. Lowe (Burton), Mr. Barron (Southport), Mr. Vincent Jackson (Wolverhampton), Mr. S. Walker (Birkenhead),

Digitized by Google

Dr. Bates (Nottingham), and Dr. Carter and Dr. Ker (honorary secretaries).

Dr. Strange having been appointed chairman, Dr. CARTER read letters of apology for non-attendance, some of which contained suggestions for the meeting, some nominated candidates, and others expressed the desire that certain gentlemen should be nominated.

The CHAIRMAN said that the meeting was of the committee of gentlemen who had signified their desire to act on a general committee for the purpose of hearing names of candidates for the three seats on the Medical Council and to deliberate on these names. To put the meeting in order the circular convening the assembly was then read, which stated that the object of the meeting was to "ascertain the wish of the medical profession as to the most suitable representatives to return to the Medical Council."

Dr. CARTER explained that invitations to the meeting had only been sent out to those gentlemen who had already expressed a desire to be members of the General Committee. That General Committee had been formed by invitations to the extent of 1167, which he and Dr. Ker as hon. secretaries had sent out.

The CHAIRMAN then formally opened the meeting. After a very long struggle, he said, on the part of the members of the Reform Committee of the British Medical Association, and particularly of the Committee's chairman, Dr. Waters, they had obtained the Amended Medical Act. That Act conferred on the profession privileges hitherto denied them. In the original draft of the Bill two representatives on the Medical Council were accorded to England and Wales, one to Scotland, and one to Ireland. By the efforts of Sir Walter Foster the English representation was increased to three. The selection of the first three representatives was decidedly an epoch in the history of the profession. Hitherto the professional representation had been confined to the universities and Royal Colleges, and the representatives on the Medical Council thus sent might be men of eminence and trusted representatives of the great bodies that sent them, still they were not representative of the general practitioners of the country, and they were not representative of the universality of the profession. Now, however, this universality of representation would be secured by the amended Act; and he hoped the general practitioners of the country would return to the Medical Council men who were in harmony with the general feeling of the practitioners throughout the country. They were assembled now to ascertain what would be the best means by which they should select these three representatives. In a vast body like the medical men of England and Wales, numbering over 20,000, it would be an extremely difficult matter to manage an election at all, and all the more difficult in that they had no organisation or settled plan by which they could decide as to the merits of the respective candidates. He thought they should endeavour to get representatives who from their position in the profession and for the work they had done would secure the confidence of all—men, too, who had leisure to do the duties thoroughly. He need not say anything about the origin of the present meeting. It was of no consequence what had been done in the past—what took place at Brighton,—because they had now done what was originally intended, they had applied to the whole profession. Something like 1000 or 1100 circulars had been sent out inviting gentlemen to take part in the General Committee, and over 200 representatives had answered the circular from upwards of 100 towns and villages. They could not therefore be accused of cliquism, and the present meeting was thoroughly representative of the profession. They might therefore proceed at once to consider the claims of certain persons who would be presented to them, and to put the proceedings in order he would call upon Dr. Eyton Jones to propose a resolution.

Dr. EYTON JONES then moved "That this meeting, fully impressed with the extreme importance of the present crisis in the history of the English medical profession occasioned by the right acquired in the recent Medical Act of electing three representatives of their body on the General Medical Council, deems it expedient to proceed at once to deliberate on the merits of the various candidates for such representation, and to solicit by requisition three fit and proper persons to undertake the office." As the British Medical Association was originally a provincial organisation, and as the General Medical Council had in the past been represented by men taken from the centres of learning—London, Edinburgh, and Dublin,—now the medical practitioners of the provinces should be represented by the three additional members they had to select as a balance, though a small one, against those that had hitherto been selected by the Universities and the Corporations, and nominated by the Government. They should show in so far as they could in their selection of these three candidates their desire to have a voice in the legislative body of the profession, and they should therefore select men who knew the conditions and the necessities of the general practitioner, and who would speak up for them manfully and openly on the General Medical Council. (Applause.) The Council had hitherto acted principally in the direction of the education of the future practitioners, and in consequence, the rights of the present practitioners had suffered. Many questions would crop up when they had popular representation on the Medical Council, and they should have representatives on it who would be able to take their part because they themselves had experienced their grievances.

Mr. LAWSON TAIT, in seconding the resolution, said he could not help feeling that it was but a scant reward for the trouble Dr. Ker and Dr. Carter had taken in sending out so many circulars to find that so few should have expressed their enthusiasm in the question by attending the meeting, and thus leaving in the hands of these few the responsible work of selecting the first three representatives to the General Medical Council. He for one had not great enthusiasm in that direction, because he thought their efforts might have been better directed towards the reconstruction of that General Council. It seemed to him a great waste of money and of time for people to be appointed on that Council, whose only duty appeared to be to meet together and make long speeches, people who had no connexion and no sympathy with the medical profession, and who know nothing about its wants or its abuses. (Hear, hear.) He accepted the political principle of having direct representation to a small extent on the General Council, and he trusted his fellow practitioners would exercise due discretion in the selection of the candidates they sent to represent them. He hoped they would not select representatives who were in the clouds of the medical profession, men who had little association with the feelings or the aspirations of the bulk of the practitioners in the country; also that they would not choose their representatives merely by their seniority. (Applause.) What they wanted was three men who would expose and try to reform a great many of the abuses in the General Medical Council. (Hear, hear.)

At the request of Dr. Danford Thomas, Dr. CARTER stated that the number of responses received to the circular to take part in the General Committee for the selection of the candidates was 343 up to that day, and that number represented 161 towns from all parts of England and Wales.

The CHAIRMAN, answering a second question of Dr. Danford Thomas as to whether the meeting intended to select right off three representatives, said that at the present the meeting was very small, but he hoped it would enlarge to enable them to take some decisive action. The resolution now proposed did not necessarily bind the meeting to select three representatives then.

Dr. DANFORD THOMAS.—We are not yet twenty-five.

Dr. KER.—I have counted thirty-two. (Laughter.)

The CHAIRMAN did not think they should hesitate about proceeding, because the business of the meeting was to discuss the merits of candidates to be nominated. He did not expect more than fifty to attend the meeting, and those that were present were thoroughly representative.

Mr. NICHOLSON said that the meeting might be adjourned considering the sparse attendance, and that its duties should be relegated to a small committee. Some present had travelled long distances, and did not like the idea of adjournment.

The resolution was then put to the meeting, and carried.

Dr. CARTER then proceeded to read the correspondence he had received containing suggestions and proposing candidates. There was a sort of honourable understanding, he said, that every name that had been before the profession, whether sent to Dr. Ker or himself as the secretaries of that committee, or mentioned in any of the medical journals, should be put before the meeting. One suggestion made was that all the representatives should be general practitioners only, another that the present meeting should be preliminary to another, which would make the final selection. (Hear, hear.) Dr. Taaffe of Brighton wrote saying he was a candidate for the representation, and asking to be

brought forward as such. Dr. Stokes of Highbury, London, wrote, as chairman of a committee who were forwarding the candidature of Dr. Glover of London, asking how that gentleman's name could be brought before the present meeting, and a correspondence had taken place between him (Dr. Carter) and Mr. Stokes on the matter. He says "that Dr. Glover's name would be sure to be brought forward. Dr. Sympson of Lincoln and others had also written recommending Dr. Glover's candidature. Dr. Partridge and Dr. Shuttleworth of Lancaster and others had suggested Sir B. Walter Foster as a candidate. (Hear, hear.) A memorial had been sent up from Cambridge in favour of Dr. Bridger, and others recommended by letter were Mr. D. B. Balding of Royston, Dr. Dolan of Halifax (who was strongly recommended by Dr. Rabagliati of Bradford), Dr. B. W. Richardson, Mr. Wheelhouse of Leeds, Mr. Hart of London, Sir Andrew Clark, Mr. Holman of Reigate, Dr. Waters of Chester, Dr. Harrow, and Dr. Morris of Spalding.

In answer to Dr. Danford Thomas, the CHAIRMAN said they had no intimation from any of the candidates that they would stand if elected.

Mr. NICHOLSON suggested that the best way to proceed would be for the secretary of the committee to make out a list of all the nominations to be sent to every member of the General Committee, and each member to send back his list with the three names marked that he approved of. He thought this all the more desirable, seeing the small dimensions of the present meeting. For his own part, he believed Mr. Wheelhouse of Leeds would represent best the practitioners of the north of England. (Applause.) He was a thoroughly representative man, and, he believed, would be elected. He would put his suggestion into the form of a resolution.

On this intimation, Dr. WATERS said he would second it.

The CHAIRMAN asked Mr. Nicholson to abstain from bringing forward his resolution till after the nominations. So far, the thing had only taken the shape of suggestions. Besides, others were eligible for candidature besides those suggested by letters received. Anyone at that meeting could propose whomsoever he chose. By the resolution already passed, too, they had resolved to deliberate upon the names brought forward.

Mr. NICHOLSON consented to postpone his resolution till the nominations were completed.

Dr. BARRON then said he thought it would be highly desirable to divide the whole of England into three divisions, the north, the midlands, and the south. (Hear, hear.) A candidate that might suit the practitioners of the south of England would not necessarily suit the north, and *vice versâ*. He therefore advocated this division of the country with the object of each division securing a representative that would be thoroughly representative of its practitioners by his personal knowledge of their different necessities and grievances.

Mr. VINCENT JACKSON highly approved of Dr. Barron's suggestion. By such an arrangement the work of selection would be made very much easier; they would be likely to get representatives who would please everyone, and the selection would be greatly simplified.

Dr. WATERS said there was no advantage to be obtained in dividing the country into three divisions, for they could not divide the electorate with it. Each practitioner in each division would be able to vote for three candidates; they could not restrict him to vote for one for his division only.

Mr. LAWSON TAIT said the proposition appeared to him absurd and illogical. He could not imagine anything more likely to defeat the object they had in view than such a division of the country. He suggested that, without regard to location, they should select three of the most active, young, and discontented men in the profession, the more active and discontented the better. (Laughter and applause.) They wanted the General Medical Council reformed, and these were the sort of men to do it.

The CHAIRMAN said it was almost the first time in his life he had differed with Mr. Lawson Tait, but he differed with him on that point. It might be a little childish and somewhat illogical; but he believed it would enable them to secure the best men.

Mr. BARRON objected to the suggestion being characterised as either childish or illogical. He would not have proposed it if he had thought it either of these; but, on the contrary, he considered it very good sound sense.

The CHAIRMAN.—I will withdraw the word "childish" if Mr. Tait will withdraw the word "illogical."

Mr. TAIT.—I will withdraw it if you wish it, but the withdrawal does not alter my opinion.

After a deal of desultory discussion as to the procedure in the selection of the representatives, it was at length decided to proceed with the nomination of candidates.

Dr. EXTON JONES proposed Mr. Wheelhouse of Leeds, and after Dr. Berry had interposed with a question as to where the expenses for the election were to come from, Mr. Nicholson seconded the nomination, saying he felt sure Mr. Wheelhouse would be elected by the votes of the north of England practitioners.

Dr. DONOGHUE doubted whether Mr. Nicholson was quite correct in his estimate of the vote that would be given to Mr. Wheelhouse in the north of England.

Dr. Glover, of London, was next proposed by Mr. KER, and seconded by Dr. WHEELHOUSE, who said that if any man knew the requirements of the profession Dr. Glover did.

Mr. LAWSON TAIT thought that considering his connexion with THE LANCET, and the part that Journal had taken in bringing about the amendment of the Medical Act, Dr. Glover should certainly be one of the three chosen representatives. He was sure to be on the discontented side of the question.

Sir Walter Foster was the next nomination, the nominator being Mr. NICHOLSON, and the seconder Dr. BARRON. Dr. Barron said if it was only to show their gratitude for the increased representation they had got by Sir Walter Foster's exertions, they should elect him as a representative.

Mr. ARMSTRONG next nominated Dr. Dolan, of Halifax; and the others put forward were Mr. Hart, of London, by Dr. WATERS; Dr. B. W. Richardson, by Dr. DANFORD THOMAS; Dr. Bridgewater, of Harrow, by Mr. NICHOLSON; and Dr. Holman, of Reigate, by Dr. WATERS.

Cries of "Vote" were then raised, and as several gentlemen had left the meeting while the nominations were taking place, Mr. NICHOLSON said it would be absurd, under the circumstances, to take a vote. The other names suggested by letter for candidature, but not formally proposed, were then read over, and Dr. Balding of Reigate and Dr. Morris of Spalding found nominators, but no one put forward the name of Dr. Taaffe of Brighton.

Mr. NICHOLSON then proposed that the names thus nominated at the meeting be sent to all the members of the General Committee, and the vote on them be taken by post-card, the three that received the highest number of votes to be the adopted candidates of the committee for representation on the General Medical Council.

After some discussion as to this resolution clashing with the one already passed, it was decided to entertain it, and, on the vote being taken, it was carried by 11 votes to 3, many of those present at the earlier part of the meeting having left.

The meeting was then concluded with a vote of thanks to the chairman for presiding.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5784 births and 3939 deaths were registered during the week ending Sept. 11th. The annual death-rate in these towns, which had steadily increased in the preceding four weeks from 18·9 to 20·8, further rose last week to 22·6. During the first ten weeks of the current quarter the death-rate in these towns averaged 20·1 per 1000, and was 1·5 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 13·9 in Bristol, 16·5 in London, 19·1 in Plymouth, and 20·0 in Huddersfield. The rates in the other towns ranged upwards to 31·9 in Nottingham and in Bolton, 34·8 in Leicester, 35·1 in Norwich, and 38·1 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 778 and 931 in the preceding two weeks, further rose last week to 1199; they included 995 from diarrhœa (exclusive of 21 attributed to simple cholera), 50 from whooping-cough, 49 from "fever" (principally enteric), 46 from scarlet fever, 38 from measles, 20 from diphtheria, and 1 from small-pox. The lowest death-rates from these zymotic diseases were recorded last week in Bristol, London, and Plymouth; and the highest in Nottingham, Hull, and Norwich. Diarrhœa caused the highest death-rates in Leicester, Preston, Hull, and Norwich; whooping-cough in Preston; scarlet

Digitized by Google

fever in Salford and Huddersfield; "fever" in Norwich and Portsmouth; and measles in Nottingham. The 20 deaths from diphtheria included 9 in London, 2 in Portsmouth, 2 in Liverpool, and 2 in Salford. Small-pox caused 1 death in London and its outer ring, but not one in any of the twenty-seven large provincial towns. No small-pox patients were under treatment in the metropolitan asylum hospitals situated in and around London. The deaths referred to diseases of the respiratory organs in London, which had been 160 and 128 in the preceding two weeks, further fell last week to 110, which were 58 below the corrected average, and considerably fewer than those returned in any previous week of this year. The causes of 99, or 2·6 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bradford, Sunderland, Portsmouth, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Salford, Sheffield, and Oldham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·7 and 19·4 per 1000 in the preceding two weeks, further rose to 20·6 in the week ending September 11th; this rate was 2·0 per 1000 below the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 13·1 and 15·7 in Perth and Dundee, to 24·3 in Paisley and 28·0 in Aberdeen. The 508 deaths in the eight towns last week showed an increase of 21 upon the number in the previous week, and included 57 which were referred to diarrhœa, 20 to whooping-cough, 7 to scarlet fever, 4 to "fever" (typhus, enteric, or simple), 4 to diphtheria, 1 to measles, and not one to small-pox; in all, 93 deaths resulted from these principal zymotic diseases, against numbers increasing from 63 to 86 in the preceding four weeks. These 93 deaths were equal to an annual rate of 3·8 per 1000, which was 3·1 below the mean rate from the same diseases in the twenty-eight English towns. The deaths referred to diarrhœa, which had been 23, 36, and 53 in the previous three weeks, further rose last week to 57, of which 20 occurred in Glasgow, 9 in Dundee, and 7 in Aberdeen. The annual death-rate from diarrhœa in the eight Scotch towns last week did not, however, average more than 2·3 per 1000, whereas the mean rate from the same cause in the twenty-eight English towns was 5·7. The fatal cases of whooping-cough, which had been 22, 19, and 10 in the preceding three weeks, rose again last week to 20, of which 15 occurred in Glasgow. The 7 deaths from scarlet fever, all of which were returned in Glasgow, showed a further decline from the numbers in the previous two weeks. The deaths referred to "fever" had also declined, and the fatal cases of diphtheria were also below the average. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 67 and 56 in the preceding two weeks, rose again last week to 72, and exceeded by 15 the number in the corresponding week of last year. The causes of 72, or more than 14 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 18·2 and 26.2 per 1000 in the preceding two weeks, declined again to 25·9 in the week ending Sept. 11th. During the first ten weeks of the current quarter the death-rate in the city averaged 21·2; the mean rate during the same period was 19·3 in London and 18·2 in Edinburgh. The 175 deaths in Dublin last week showed a decline of 2 from the number in the previous week, and included 26 which were referred to diarrhœa, 7 to scarlet fever, 4 to "fever" (typhus, enteric, or simple), 1 to whooping-cough, and not one either to small-pox, measles, or diphtheria. Thus 38 deaths resulted from the principal zymotic diseases, against 18 and 22 in the preceding two weeks; they were equal to an annual rate of 5·6 per 1000, the rates from the same diseases last week being 3·4 in London and 2·0 in Edinburgh. The fatal cases of diarrhœa, which had been 9 and 14 in the preceding two weeks, further rose last week to 26, and exceeded the number in any previous week of this year. The 7 deaths from scarlet fever also showed an increase upon recent weekly numbers; whereas the 4 deaths from "fever" showed a decline of 4 from the number in the previous week. Three inquest cases and 4 deaths from violence were registered; and 29, or one-sixth of the deaths, were recorded in public institutions. The deaths of infants showed a further increase upon the numbers in recent weeks, while those of elderly persons had slightly declined. The causes of 39, or more than 22 per cent., of the deaths registered during the week were not certified.

"Audi alteram partem."

CHOLERA AND THE WATER-SUPPLY OF MADRAS.

To the Editor of THE LANCET.

SIR,—At a time when cholera is such an interesting question in England, the following table, showing the decrease in mortality in an Oriental town from this pest since it has been favoured with a comparatively pure water-supply, may not be without interest. The Red Hills tank is a large sheet of water some ten or twelve miles from Madras. It is a rain-fed tank, and not cleaner than such tanks, undefiled, would be; but it has this advantage: it has no villages near it, it is away from any thoroughfare, and consequently undefiled by foot-passengers and pilgrims; it is, moreover, scrupulously conserved. The water is led into Madras, first, by a channel more or less well protected, and then the water is distributed over the town by pipes. Even the deaths which have occurred in Madras are found to have mostly taken place in outlying parts of the town, where the Red Hills water has not yet been laid on, except in one district, Triplicane. Here live a large number of Mussulmans, and their women, being Gosha—i.e., not allowed to be seen by any but their own family,—are obliged to draw their water from small wells in their back-yards, always perilously near the cesspits.

Return showing the deaths from Cholera in the Town of Madras from 1855 to 1884.

Year.	Deaths from cholera.	Remarks.
1855	1956	—
1856	805	—
1857	1378	—
1858	1965	—
1859	1082	—
1860	2580	—
1861	2776	—
1862	3635	—
1863	1684	—
1864	574	—
1865	944	—
1866	2984	—
1867	614	—
1868	13	—
1869	568	—
1870	861	—
1871	493	—
1872	5	Red Hills water-supply opened.
1873	6	—
1874	0	—
1875	879	Famine years.
1876	2035	Famine years.
1877	6246	Famine years.
1878	64	—
1879	34	—
1880	2	—
1881	123	A very severe epidemic throughout the Presidency.
1882	361	A very severe epidemic throughout the Presidency.
1883	168	A very severe epidemic throughout the Presidency.
1884	269	A very severe epidemic throughout the Presidency.

During 1881–84, the Madras Presidency was visited with one of the severest epidemics of cholera on record, and yet it will be seen that the mortality in Madras city itself was comparatively slight. Two or three times it reappeared in the town coincidentally with the return of pilgrims from

Digitized by Google

some religious gathering, but it died out. During the four years, the European community were singularly free. I can remember only two cases, and, oddly enough, one of these was a teetotaler. The famine years are scarcely worth taking into consideration; during 1876 and 1877, the people from surrounding districts simply flocked in to die. Every case almost was called cholera; it was simple, and saved trouble.

Such a table as the above points, I think, very forcibly to the advantages which would accrue from having every town in India furnished with a pure water-supply; and this, with the authority of Government, might easily be carried out.

I am, Sir, yours truly,

Madras. M. C. FURNELL, M.D., Surg.-Gen.

"SPAYING," OR REMOVAL OF THE UTERINE APPENDAGES?

To the Editor of THE LANCET.

SIR,—The fact that you have devoted a leader to this question of nomenclature shows that you agree with me at least in its importance. I object to the term "spaying" because it is altogether a false term, and I think you will allow me to argue this view as briefly as I can.

First of all it is false, because in spaying animals the Fallopian tubes are not removed habitually; that is, some of those who operate on the animals do remove the tubes and others do not, a fact of which I have satisfied myself by actually seeing it done. The removal of the ovaries only of an infantile animal seems quite enough to prevent the changes of puberty. Removal of the ovaries alone in cases of myoma and chronic inflammatory disease of the appendages of adult women would not be enough to procure the desired results, and very often the ovaries may be left with distinct advantage if the tubes are thoroughly removed. I have published quite enough on this subject to satisfy any reasonable inquiry, and I have much more material nearly ready for publication, the conclusions from which are all in the same direction. The very pathological changes induced by the diseases for which the operations are performed, as proved by numerous specimens exhibited at many societies, establish anatomical differences enough to make us regard "spaying" as an operation quite different from "removal of the uterine appendages."

You say that an operation should be named not by reason of the motive with which, or the purpose for which, it is done, but according to its nature from an anatomical point of view. Will you permit me to say that I think you have hardly sufficiently considered the effect of such a conclusion, as you may come to an altogether different opinon if you apply your principle in other directions. Thus the harikari of the Japanese Daimio and the abdominal section of an approved operation are, *anatomically*, quite the same. Are we therefore to speak in a serious medical journal of them both as "belly-ripping?" Would you seriously undertake to publish a paper of mine with the title—"A Series of Five Hundred Consecutive Belly-rippings"?

The operation performed by the obstetric physician for the induction of premature labour and the illegal proceedings of the abortion-monger are, *anatomically*, exactly the same, yet is not the nomenclature *entirely* influenced by the "motive with which, or the purpose for which," these operations are undertaken? Would not a jury and a judge take motive and purpose very prominently into account as to the definition and means of each of these operations?

Again, you say that "spaying" does not consist in the removal of an ovary still functionally active, and this, being quite true, is the basis of my objection to the application of the word in human surgery. "Spaying" is the removal of both ovaries long before they are functionally active. "Removal of the uterine appendages" is an operation for the removal of either one or both ovaries or tubes long after they have become functionally active; and from these facts alone there is an immense anatomical difference between the two operations, which makes a common nomenclature alike impossible and improper.

You say that "spaying" is the removal of both ovaries; how is it possible, then, to class under such a word a case where one or both tubes are removed as chronic abscesses, the ovaries being left? How am I to class under it a case where I remove one tube for a ruptured tubal pregnancy and leave both ovaries? Or if we happen to remove both ovaries for large cystic tumours, are we still to call it a case of "spaying"? The advantage of the term I advocate is, clearly, that it is comprehensive, and admits of classification in a much more orderly fashion than can be done in any other way. And let me here say that I entirely agree with you that to speak of Battey's, or Tait's, or Hegar's operations is very foolish, and is productive of endless confusion. I have never ceased to protest against it so far as my own name is concerned, and for a very simple reason, which I have put on record very many times. Battey originally proposed the operation of removing the ovaries in cases where there was no actual disease of them for the purpose of indirectly influencing neurotic conditions. My first operation was removal of a small ovary, the subject of an abscess; my second, the removal of the appendages for uterine myoma; and to these and similar physical conditions I have, with a very small number of exceptions, confined my work. Hegar's proceeding was for myoma entirely. To speak, therefore, of all operations for removal of the appendages by any one of the three names is to commit an absurdity.

Of course every woman submitted to an operation should be made aware of what is really going to be done to her, not only in this instance but in every other; and not only every woman, but every man: that is, they should be made to understand it as fully as their intelligence admits of. This view really constitutes the greatest argument against the use of the word "spaying," for it is "understanded of the people" as having intentions and results so absolutely foreign to the intentions and results of "removal of the uterine appendages," that I am not at all surprised at the row in Liverpool, and the unusual results brought about by it, now that we have an admission from Dr. Grimsdale of what he has been doing and saying. When I heard him say in the witness box that "ovariotomy did not necessarily include removal of the ovary," I suspected he was living in an atmosphere of confusion; now I know he has created it, and, by his own confession, he is responsible for results deeply to be regretted, not only for abdominal surgery but for the credit of the whole profession. In his evidence, Dr. Grimsdale clearly threw blame on Dr. Imlach for performing operations without consultations. If Dr. Imlach did this, then Dr. Grimsdale was clearly to blame for it. As consulting officer to the hospital, he could have insisted on consultations being held, and if they had been refused his remedy lay in an appeal to the Committee of the Hospital by a complaint that an important law was broken and defied. Instead of this he appealed to outside authority in such fashion as led to most discreditable proceedings.

I am, Sir, yours truly,

Birmingham, Sept. 4th, 1886. LAWSON TAIT.

To the Editor of THE LANCET.

SIR,—Had not Dr. Imlach made indirect reference to the other members of the staff of the Liverpool Hospital for Women in your issue of Sept. 4th by saying that he was the only one of them who had performed the operation of castration for hæmatocele and hæmatosalpinx, I should not have intruded into this discussion. I am proud to say that Dr. Imlach's statement is perfectly correct as far as I am concerned, and I believe also as regards Dr. Lupton, who is suffering from a lingering illness and unable to answer for himself. I have never performed spaying operations for either hæmatocele or hæmatosalpinx. It is also a fact that I have never yet lost a patient from either of these diseases, nor had one that did not completely recover.

Being, however, surgeon to the same hospital, I must necessarily have had to treat the very same classes of cases as Dr. Imlach, and if in the space of three years he has had a considerable number of these cases, it follows almost as a matter of course that I have also treated a considerable number, unless it has happened that they all went to him, and consequently none to me. I do not believe this has been the case. The case stands thus, then: Dr. Imlach has treated a certain number of these cases by mutilation, with three deaths, and I, in common with large numbers of surgeons, have treated a number nearly as large, with not only no deaths and no mutilation, but with complete recovery and without abdominal section.

I will concede that the laparotomist has one advantage over the surgeon who treats his cases in less sensational ways: his diagnosis is more accurate; and this is so from the fact that the laparotomist makes his diagnosis by open-

Digitized by Google

ing the abdomen. We have no evidence whatever that these cases were diagnosed before the abdomen was opened. Let us suppose for a moment that the abdomen had not been opened in these cases of Dr. Imlach's—the diagnosis would then have been incomplete; but the cases would have been none the less cases of hæmatocele and hæmatosalpinx, and by another surgeon would have been treated with complete success on ordinary lines. Great numbers of these cases are treated under their own or different names every year, and the patients are perhaps all the better for the doubt in the diagnosis. The surgeons who perform abdominal section in these cases do not do it *for* these diseases—i.e., knowingly,—but because the symptoms point to *something* being wrong in the pelvis. They do not know what the "something" is, but, opening the abdomen before the morbid condition has had time to right itself, they are equally surprised at the discovery they have made and proud of the achievement. The accuracy of diagnosis after opening the abdomen is, I grant, admirable; but, to my mind, this does not compensate for the inevitable loss of life that attends the making of it. I am, Sir, yours obediently,

J. E. BURTON,
Surgeon to the Hospital for Women, Liverpool.

Liverpool, Sept. 7th, 1886.

To the Editor of THE LANCET.

SIR,—In reply to Mr. Lawson Tait's letter which appears in THE LANCET of the 21st ult., wherein he states that the operation of spaying an animal and the removal of the uterine appendages from the human being have no conceivable resemblance, consequently to talk of spaying women "is to display great ignorance or to indulge in wilful misrepresentation for purposes of giving offence," I beg to say, with all due respect to that gentleman, that I differ from him. I have spayed some thousands of animals—both those that have not and those that have arrived at puberty. In the latter subjects the ovaries only are removed; in the former the uterine appendages are removed altogether, and it is an undoubted fact that after such an operation has been performed it rarely does destroy the sexual powers and desire, providing the operation has been performed properly; but if there is a small portion of the ovary, or "pride," which it is commonly called, unremoved "or not clean cut," then there will be an over-excess of desire left. If the ovaries only or the uterine appendages altogether are removed, the subject is really spayed or castrated; and the same term will apply to the human being as well as the brute.

I am, Sir, yours faithfully,
Cranham-road, Sept. 1886. C. E. ONSLOW, Vet. Surg.

"THE DIRECT REPRESENTATION OF THE PROFESSION."

To the Editor of THE LANCET.

SIR, May I be allowed to reply to your correspondent who asks why Birmingham was selected as the place of meeting of the committee formed at Brighton? It was simply because that town was thought to be the most centrally situated and generally accessible of all the large towns in the kingdom. Many places were mentioned, but none other seemed on the whole so convenient, and hence it was ultimately selected. The committee, which is now a very large one and comprises numerous representatives from no less than 124 towns and districts of England and Wales, has but a single aim, and that is to endeavour by consultation to ascertain what three medical men would be likely most efficiently to defend the interests of the great body of general practitioners in the General Medical Council. It shrinks from any attempt, and hopes that it may not be thought to have the slightest desire, to dictate. Its aim is consultative. It invites every registered medical practitioner to give it the benefit of his opinions and advice in this most important matter. There must be some kind of organisation unless votes are to be given aimlessly. Organisations already exist. This one, being absolutely unpledged, aims at ascertaining the wishes of the profession; when it has ascertained them, it hopes by concerted action to be able to give effect to them.

I am, Sir, yours faithfully,
Liverpool, Sept. 6th, 1886. WILLIAM CARTER.

*** We regret that, owing to the number being specially devoted to educational matter, we were unable to insert this letter last week.—ED. L.

THE HOSPITAL FOR WOMEN, LIVERPOOL.

To the Editor of THE LANCET.

SIR,—The first paragraph of Dr. Imlach's letter in your issue of September 4th is both incorrect and misleading. I did not at the Casey *v.* Imlach trial "state on oath that the mortality in cases where this operation—i.e., abdominal section had been performed at the Hospital for Women was 33 per cent.," as Dr. Imlach says I did. What I did say was, that the operation to which Mrs. Casey was subjected—i.e., the removal of the uterine appendages for hæmatocele and hæmatosalpinx, an operation to which abdominal section is but the necessary preliminary or exploratory incision—had been fatal in the Hospital for Women during the year 1885, as shown by the Annual Medical Report, in the ratio of 33 per cent. In support of this assertion, I do not intend to follow Dr. Imlach in his vain endeavours to mystify or evade the single point at issue, but will content myself with giving an exact copy from the Report itself of every case in which during the year 1885 Dr. Imlach removed the uterine appendages on one or both sides—i.e., partial or complete spaying—for pelvic hæmatocele or hæmatosalpinx. This Annual Medical Report of the Hospital for Women, Shaw-street, Liverpool, for 1885, was written entirely by, or under the immediate direction of, Dr. Imlach, and must therefore be held to be a sufficient authority for the statements taken directly from it.

Thus it will be seen from Dr. Imlach's own Report, given in a tabular form, that the whole number of cases of pelvic hæmatocele and hæmatosalpinx in which the uterine appendages were removed during the year 1885 amounted to 9, of which 3 died and 6 recovered—a mortality of 33·3 per cent.

I am, Sir, yours truly,
September 9th, 1886. THOMAS F. GRIMSDALE.

COPIED FROM TABLE III. TO ANNUAL MEDICAL REPORT FOR 1885, HOSPITAL FOR WOMEN, LIVERPOOL.

THE SURGICAL REPORT ON THE BELFAST RIOTS.

To the Editor of THE LANCET.

SIR,—Kindly allow me space for a personal explanation. Commenting on the summary of my Report, you state it is your "impression that Mr. Foy under-estimates the number of those injured in the riots." Nothing was more difficult to avoid than exaggeration in preparing my report, which I may incidentally remark was for your contemporary, the *Medical Press*. I was told of hundreds killed, of many bodies buried in back yards, of dozens of insurance agents requested not to ask for medical certificates, of congregations that counted their losses by scores, &c. Of the wounded, if I had believed what I was told, the Shankhill-road fight was more terrible than Plevna. But I was not going to print loose statements, and as I was actually in one of the riots in the Shankhill-road, and read the following day's Belfast papers, I saw that the reports did not minimise the incidents of the night. The cemetery returns, the doctors' lists, the statement of the rector and curate of one of the largest congregations (one which was said to have suffered dreadfully), and the personal introduction into the disturbed districts of the most trusted men of both sides, were all utilised to aid me in forming an approximation to the truth. As for the statement that many bodies were buried in back yards to avoid medical certificates—a statement which is freely made by artisans in Belfast, and appears to be credited by many,—I think it is unwarranted. With most diligent searching I could not find a single such grave. As for the wounded, I only counted such cases as required surgical care. Of the 322 police "more or less injured," I do not hesitate to say that the "less" form the enormous majority.

I am, Sir, yours faithfully,

Dublin, Sept. 4th, 1886. GEORGE FOY.

To the Editor of THE LANCET.

SIR,—Permit me to point out an error into which you, in common with several newspapers, have fallen in ascribing this Report to the initiation of the Loyal and Patriotic Association. In your issue of Sept. 4th you quote largely from this Report, prefacing the same with the remark that it is "just presented by Mr. Foy, F.R.C.S., the surgical commissioner sent down by the Irish Loyal and Patriotic Union to inquire into the nature of the injuries," &c. Mr. Foy went solely as our special commissioner, to report exclusively on behalf of the *Medical Press and Circular*, and was in no sense the commissioner for any political association; and his report appears in full in the above journal for Sept. 1st. The mistake probably arose from the fact of the Loyal and Patriotic Union having, with our permission, reprinted the Report in pamphlet form and circulated it throughout the country. This correction has now been made in the House of Lords, during debate, and in *The Times* and several leading newspapers, and in justice to the *Medical Press and Circular*, I trust you will kindly allow this to appear in your columns.

I am, Sir, your obedient servant,

Sept. 1886. A. A. TINDALL, General Manager.

INFANT FEEDING.

To the Editor of THE LANCET.

SIR,—Dr. Thurstan publishes a paper in your issue of Sept. 4th on the above-named subject, in which he advocates the early use of farinaceous food in the hand-rearing of young babies. Physiology and experience both, in my opinion, negative such a plan. It is not to express this opinion that I write, but to refer to certain points in the paper which lead me to think that Dr. Thurstan's failure with cow's milk is to be explained by his method of using it. In the case quoted he states that a child recently born was fed upon "milk-and-water, half and half of each." Those accustomed to hand-rearing of infants would easily predicate what he tells us in detail afterwards. No baby certainly can be expected to tolerate milk food of such a strength at that age. Nothing is said as to the *interval* between the meals, or the *quantity* given at each meal. These two factors are of equal importance to the selection of food, and should not be ignored. The *manner* of giving the meals is also not stated. In this paper we also find that lime-water "sometimes produces sickness." How soon after the meal? Upon the answer to this question may possibly hang the solution to what, I cannot help thinking, is an error in reasoning upon the part of the observer. In the numbered diets "cream-and-water" is mentioned, and subsequently negatived for use because of the absence of caseine. Dr. Thurstan probably does not know of the admirable mixture of whey-cream-and-water (Eustace Smith), and, for after-use, of Frankland's milk. This latter preparation should at first be used, I think, more diluted with whey than Frankland suggests. The "problem we have to solve" is scarcely "how to make curd digestible," but in what way we can reduce the caseine to digestible limits in each individual case. That this can be done by one of the two methods mentioned by me is certain. Increasing experience makes me more convinced that the larger proportion of failures in the use of cow's milk is due to want of appreciation of the general principles of hand-rearing and the erratic manner in which it is given. At least an equal interest in the subject to that claimed by the writer of the paper makes me hope that Dr. Thurstan's suggestions may not be adopted.—I am, Sir, yours obediently,

LEWIS W. MARSHALL, M.D.,

Nottingham, Sept. 5th, 1886. House-Surgeon, Children's Hospital.

THE INTRA-UTERINE GALVANO-CAUTERY.

To the Editor of THE LANCET.

SIR,—In an annotation in your issue of Sept. 4th you refer to the use of the galvano-cautery in the treatment of dysmenorrhœa. I have no doubt that galvano-cautery, if applied to the cervical canal, will relieve the affection, and I should think that it would not be necessary to cauterise the entire intra-uterine wall; but a much easier and more effectual method of using electricity for the relief of the complaint named is electrolysis. This, I should say, has proved more effectual than any other method hitherto adopted. I will not enter into the question as to whether or not stenosis is the cause of the painful menstruation, but a common mode of treating the affection, even by opponents of the obstructive theory, is to dilate the os uteri. In the treatment by galvano-cautery to which you alluded, the os was first dilated, and it might be said that the relief experienced was due to the dilatation, and not to the electricity. With electrolysis no previous dilatation is necessary, and therefore the operation can be performed much more easily and without the slightest pain. No doubt after the operation the cervical canal is larger from the chemical action which takes place around the electrode. Very possibly, for the cases in which M. Apostoli is mentioned as using the galvano-cautery, it may be the best method of employing electricity. Of this I have not as yet had sufficient experience, but I am sure that for dysmenorrhœa and several other affections of the uterus for which electricity can be employed electrolysis will be found the most effectual and best form of using it.

I am, Sir, yours faithfully,

Welbeck-street, W., Sept. 1886. W. E. STEAVENSON, M.D.

ON CLERGYMAN'S SORE-THROAT.

To the Editor of THE LANCET.

SIR,—The theory propounded by Dr. Whipham with regard to one of the causes of the so-called clergyman's sore-throat, and published in THE LANCET of September 4th, will, I am sure, be acquiesced in by many who have had some of these troublesome cases to deal with; but there is another matter not mentioned by Dr. Whipham, which has certainly in more than one case under my care declared itself by contributing to the obstinacy of the attack—that is, the wearing of the stiff band-like collar now so much in use by clergymen. This I have found, when the head is bent, presses unduly across the thyroid cartilage, and at times a sharp red line on the skin may be observed after the performance of a service, showing how severe the pressure has been.

In a case lately under my care, by discarding the use of this kind of collar and wearing one open in front, more after the fashion of those which prevail amongst barristers, remedies succeeded which had hitherto failed.

I am, Sir, yours truly,

Windsor, Sept. 1886. W. B. HOLDERNESS.

INFECTIOUS PNEUMONIA IN THE VALLEY OF THE BLACKWATER.

To the Editor of THE LANCET.

SIR,—To illustrate the insanitary condition of the Blackwater valley between Farnborough and Sandhurst, I would mention the case of the family of the tenant of Ivy Cottage, Farnborough. This cottage is situated in the valley, on the estate of the Empress Eugénie, far away from any other habitation. The family were attacked with diphtheria last year. This year the mother got an ordinary cold, which rapidly developed into epidemic pneumonia, and, being weakened by a miscarriage, she died. The husband and *five* of the children have been dangerously ill with the same disease, which, so far as my experience goes, is one of very rare occurrence, never appearing except in malarious damp districts. I look upon these cases as further confirmation of the necessity for cleansing the Blackwater river at Farnborough and Sandhurst.

I am, Sir, yours obediently,

C. J. DENNY, M.D.,
Medical Officer of Health for the Adjacent District.

Milestone House, Blackwater, Farnboro' Station, March 2nd, 1886.

ARMY, NAVY, AND INDIAN MEDICAL SERVICES.

To the Editor of THE LANCET.

SIR,—At page 486 of your issue of Sept. 11th, in your notice of the Army, Navy, and Indian Medical Services, you state—"On its conclusion the surgeon on probation is gazetted to the Medical Staff or Indian Medical Service as Surgeon, with the relative rank of Captain; in the Navy the successful candidate is at once gazetted as a Surgeon." Surely you are aware that the surgeon who is a candidate for the Medical Staff is placed in a position junior and inferior to both the Navy and Indian, for in the Navy, as you say, men receive a commission at once, and in the Indian the commission bears date several months earlier than the commission of the men of the Medical Staff, so that the men who pass last in the competitive examination in London for the Navy and Indian Medical Services are senior in the Service, and remain so all their lives, to the man who passes first for the Medical Staff. If, Sir, you are not aware of this, I would refer you to the Army List; and if you are aware of it, would it not be advisable to correct the very wrong impression your notice must convey to the student who cannot understand "how these things can be." Possibly the appeal in Parliament to the Secretary of State for War to give up the cheeseparing policy as regards the Medical Staff may alter this before the next Students' Number appears.

I am, Sir, yours obediently,

September, 1886. NOUS VERRONS.

MANCHESTER.

(From our own Correspondent.)

THE SALFORD HOSPITAL.

THE extension of the Salford Hospital is rapidly approaching completion; the out-patient and accident rooms are very conveniently arranged, and exceedingly well adapted for their purposes. It is in contemplation eventually to have special departments in the institution for ophthalmic and obstetric work, &c., and accommodation is provided for the expected attendance of some of our students. Hitherto the number of beds has been below that required for recognition by the College of Surgeons, but with the extensive alterations now completing provision will be made for some 120 beds, and very probably in the near future it may become a formidable rival to the Royal Infirmary as a clinical hospital for the teaching of medical students. The whole of the additional buildings have been erected without appealing to the public for funds, these having been obtained by a bequest from the late Mr. J. Pendlebury.

THE VOLUNTEER MEDICAL STAFF CORPS.

This corps, which was inaugurated here some few months ago, has attained a fair measure of success. The first company is advancing towards completion, one squad being quite efficient, and furnished with uniform, &c. The public are asked to supply funds for the equipment of the whole of the company, in order that it may be handed over to the Government and share in the annual Government grant.

SUNDAY LECTURES.

The fifth course of "Sunday afternoon lectures" to the people was commenced last Sunday in Ancoats, one of the poorest and most crowded parts of Manchester, by Mr. A. H. Acland, M.P., who selected as his subject the "Love of Liberty." Hitherto these Sunday afternoons have been a great success, and this year's series promises to be still more successful. Many eminent and well-known names are amongst the future lecturers—the Dean of Manchester, Sir Henry Roscoe, M.P., several of the professors of Owens College, Mr. William Morris, the Hon. Auberon Herbert, Mr. Councillor Southern, Mrs. Fawcett, and many others. These attempts to bring some light and learning amongst the masses of our artisan and labouring poor deserve every encouragement and support.

COFFEE *versus* BEER.

At the recent City Brewster Sessions applications were made by several innkeepers in the neighbourhood of Shudehill Market for leave to open their houses at four o'clock in the morning. The Markets Committee have provided coffee stalls specially for the use of market people in the early morning, and the magistrates wisely refused all the applications, notwithstanding the arguments put forward "that hard-working men required something stronger in the morning than coffee." When will the lesson be learnt that alcoholic drinks afford neither strength nor nourishment.

Manchester, Sept. 7th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

THE HEALTH OF TYNESIDE.

THERE has been a marked deterioration in the state of public health here during the past few weeks. There were no fewer than fifty-seven cases of infectious disease during the fortnight ending August 28th, as appears from the reports of practitioners in the borough of Newcastle to the medical officer of health. Of this large number, thirty-eight were of scarlet fever. There was also one case of small-pox, and five persons were attacked with diphtheria. Diarrhœa also has been very prevalent and fatal in the cases of infants. In the sister borough of Gateshead there has been a very serious outbreak of the latter affection, mostly occurring amongst the children of the poor in the various towns on the Tyne. Dr. Monro, medical officer of health for South Shields, pointed out in reference to the prevalence of diarrhœa, that there had not been a single death of an infant fed by the breast. At Gateshead, at the last meeting of the Town Council, a common cause of diarrhœa and other intestinal affections was said to be the custom of fruiterers and grocers sweeping their damaged fruit into the streets, and leaving it there until the scavenger's cart came round; but in the meantime the refuse was picked up and eaten by the children.

A CURIOUS DEFENCE.

At a late sitting of the Middlesbrough County Court, Dr. M'Cuaig sued a man for one guinea for professional services. It was shown that some time since the defendant took laudanum, and the doctor was called in by defendant's housekeeper, who was also his niece. He was duly attended by Dr. M'Cuaig, and after having been walked about for five hours he recovered, but refused to pay the doctor his fee on the plea that he did not send for him. His Honour: "Did you wish to be left to die?" Defendant: "I did not want the doctor." His Honour: "You will have to pay or go to prison." Defendant: "I won't pay it at all." His Honour ordered defendant to pay 3*s.* per month, and the judgment does not certainly seem to be a severe one. A case like this is just the one to give a medical man a great deal of trouble. He goes at once, to the detriment of other practice, and perhaps is detained many hours in an endeavour to save life, and has to sue for his fee.

SUNDERLAND INFIRMARY.

The new wing which it is proposed to erect to the memory of the late Mr. James Hartley, I understand, is to be devoted to children, and for this purpose some arrangement, it

Digitized by Google

is stated, will be made to effect a combination with the Sunderland Hospital for Sick Children, which has been established for many years in Lambton-street, and which has proved such a benefit to the sick poor of Sunderland and its district. The cost of the wing is estimated to be between £8000 and £9000.

A very serious epidemic of scarlet fever is reported as prevailing at Blackdean in Weardale.

Newcastle-on-Tyne, Sept. 13th.

ABERDEEN.

(From our own Correspondent.)

THE ABERDEEN ROYAL INFIRMARY.

THE quarterly Court of Managers of the Royal Infirmary met on Monday, the 13th inst., and the sitting was chiefly occupied with matters relating to the medical staff. For the office of assistant-physician, which fell to be filled up at this meeting, there were four candidates—viz., Drs. M'Kenzie Booth, MacGregor, Rodger, and Smith. Three votes were taken before an absolute majority was obtained for the successful candidate. As the result of the first vote, Dr. MacGregor's name was struck off the list, and the final vote lay between Dr. Rodger and Dr. Smith. The latter was elected by 113 votes, against 77 given for Dr. Rodger.

Dr. Struthers then brought forward his motion: "That all the members of the medical staff be appointed by the executive, and hold office during the pleasure of the executive; that the limit of service for the visiting medical officers be restricted to fifteen years, except in the case of professors in the University engaged in clinical and pathological teaching whose services the executive may deem it expedient to continue." An amendment, practically a direct negative, was carried by a majority.

THE PROPOSED NEW CHARTER.

The court approved of the constitution embodied in the draft of the proposed new Charter as revised by the managing committee, and remitted to the committee to take all necessary steps for carrying it into effect either by obtaining a new Charter or by private Act of Parliament. A new Charter costs £700, and the estimated cost of a new Bill is £400. This is a serious matter for an institution already beset with financial difficulties. A considerable sum has been spent on the alterations of the present buildings, for their report on the sanitary condition of which, it seems, Dr. Russell of Glasgow received £52 10*s*., and Dr. Simpson, then medical officer of health for the city, £21. Mr. Esslemont protested against so large a sum, £73 10*s*., being paid to those gentlemen out of the funds of a charitable institution.

EXTENSION OF THE HOSPITAL.

The Committee of Management are still deliberating upon the plans for the extension of the infirmary buildings, and the dissatisfaction felt at the delay found expression in the motion proposed by a manager, "that the Court enjoin on the Committee of Management the necessity of coming to a speedy resolution, and presenting their final report on the matter of the hospital buildings."

Aberdeen, September 11th.

IRELAND.

(From our own Correspondent.)

ROYAL UNIVERSITY OF IRELAND.

AN account of the expenditure of this University recently issued shows that for the year ending March last the salaries of the Fellows amounted to £7765, and the travelling expenses of examiners and superintendents to £1125 As contrasted with these figures, the sum awarded in scholarships amounted to only £776, and in studentships to £475. A sum of £750 was allocated for the travelling expenses of members of the Senate; and in reference to this item, the Comptroller-General of the Receipt and Issue of Her Majesty's Exchequer states that, in answer to a letter from his department asking under what authority such expenditure was incurred, the accounting officer replied that the Standing Committee of the Senate held that they had powers under the charter and statutes founded upon the provisions of the Act 42 and 43 Vic., c. 65, to incur such expenditure. The authorities referred to in the opinion of the Auditor-General of Public Accounts do not contemplate expenditure of this character. The item referred to (£750) was for the travelling expenses of members of the committee appointed by the Senate to obtain for the Royal University of Ireland a representative in Parliament.

QUEEN'S COLLEGE, GALWAY.

The President, in his report for the past session, regrets that year by year the number of students at his College has shown a decided decrease; last year they numbered only 94, of whom 34 attended the classes in the Faculty of Medicine. In the session 1881-82 the number was 201, and for a diminution so sudden and rapid he finds an adequate cause in the dissolution of the University organisation, of which the Queen's Colleges formed a part; for the Queen's Colleges and University, though apparently distinct institutions having separate charters from the Crown, really formed but one organised whole. The library and museums are in a satisfactory condition, and the apparatus for the illustration of the principles of natural philosophy, and the collections specially devoted to the pursuits of the medical profession, are worthy of special notice. Large additions have been made to the Natural History Museum, but a conservatory for the preservation of such plants as are requisite for properly illustrating the botanical lectures is still wanting. A new room, or an extension of the anatomical room, is urgently required for histological and microscopical researches; and the President trusts that the rapid development of medical science, especially in the biological department, and its immense practical importance, will justify the solicitation that this pressing need will receive immediate attention from the Board of Works.

ADDRESS AND PRESENTATION TO MR. C. NORMAN, F.R.C.S.I.

An address was last week presented to this gentleman, who has been recently promoted from Monaghan Lunatic Asylum to the important post of resident medical superintendent of the Richmond District Lunatic Asylum. The address was given by some of his friends in Monaghan, joined by the officials of the asylum, and, in addition to the address, he was presented with a magnificent centre-piece and a claret jug.

"WAKING" THE DEAD.

At the Dublin Police-court, last week, a most revolting case of this barbarous custom was detailed. A child had died, and over its body a "wake" had been held for ten successive nights. The body, which was far advanced in decomposition, was, according to the evidence, lying on the bare boards, while night after night a mob of persons assembled, drinking, fighting, and gambling. The magistrate made a compulsory order for burial, otherwise most probably the body would not have been interred for many days afterwards.

A CENTENARIAN.

A man named Holland died a few days since in the North Dublin Union Workhouse at the alleged age of 105 years. About three months previously to his death he was attacked with pneumonia of a serious character, but recovered. His death was due to a severe attack of choleraic diarrhœa. It may be mentioned that the deceased was an inveterate smoker and used the strongest tobacco.

Dr. J. O'Callaghan, medical officer of Johnston dispensary district, has been unanimously elected medical officer of Dunmanway Union Workhouse.

Mr. Werner has been appointed ophthalmic surgeon to the Mater Misericordiæ Hospital.

The late Mr. Archibald Gardiner has left, after the death of his wife, £500 to the Belfast Royal Hospital.

HARROGATE BATH HOSPITAL AND CONVALESCENT HOME.—The foundation-stone of the new building in connexion with this institution was laid on the 9th inst. The Bath Hospital will afford accommodation for seventy-five patients, and the Convalescent Home for fifty inmates. The estimated cost is £17,000, of which £15,300 has already been subscribed. Owing, however, to the sloping nature of the ground and the fact that the danger of interfering with the springs has necessitated extensions of the original designs, the estimated cost will probably be somewhat exceeded.

Digitized by Google

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Surgeon Edward Hawke Locker has resigned his commission.

INDIA OFFICE.—The Queen has approved of the following promotions among the officers of the Staff Corps and Indian Military Forces, made by the Governments in India:—Brigade Surgeon James Howard Thornton, C.B., of the Bengal Medical Establishment, to be Deputy Surgeon-General; Surgeons-Major Henri Jules Blanc, M.D., and William Dymock, of the Bombay Medical Establishment, to be Brigade Surgeons.

ADMIRALTY.—The following appointments have been made:—Surgeon James Clibborn, to the *Indus;* Surgeon Charles J ames, to the Plymouth Division Royal Marines; Surgeon William S. Lightfoot, to the *Téméraire;* Surgeon Bowen S. Thends, to the Haslar Hospital; Surgeon Horatio S. R. Sparrow, to the *Victor Emanuel;* Surgeon George F. Dean, to the *Polyphemus;* and Surgeon William W. Pryn, to the *Hotspur.*

ENGINEER VOLUNTEERS.—1st Newcastle-on-Tyne and Durham: Richard Knox Tait, Gent, to be Acting Surgeon.

RIFLE VOLUNTEERS.—1st Volunteer Battalion, the Royal Fusiliers (City of London Regiment): Henry Geo. Thompson, Gent., M.D., to be Acting Surgeon.—2nd Volunteer Battalion, the Worcestershire Regiment: Surgeon W. S. Batten, the resignation of whose commission has already been announced, is granted the honorary rank of Surgeon-Major, and is permitted to wear the uniform of the battalion on his retirement.

MEDICAL NOTES IN PARLIAMENT.

Honorary Surgeons in India.

IN the House of Commons on the 9th inst., Mr. Lawson asked the Under-Secretary of State for India whether he was aware that under a Government resolution, dated Bombay, Jan. 12th, 1881, it was ruled that no more medical subordinates would be promoted to honorary commissions unless they had obtained medical diplomas; that three warrant medical officers came to England under this rule, and, after much study and expense, obtained English medical diplomas, and that on their return to India the rule was abrogated by the decision that no further promotions would be made to the rank of honorary surgeon; and whether, considering the circumstances under which they acted, he would take steps to procure their promotion to the honorary commissioned rank under the rule of Jan. 1881.—Sir J. Gorst, in reply, stated that in 1884, on a reorganisation of the subordinate medical establishment, the selection of warrant officers for the post of honorary surgeons was put an end to on public grounds; but, instead, certain other privileges were conferred on the department to which the warrant officers belong. There was, in the opinion of the Secretary of State, no reason for making an exception in the case of the three officers referred to.

The Asylums Board.

In reply to Mr. Pickersgill, Mr. Ritchie stated, with regard to the representation of the Metropolitan Union on the Asylums Board, that an order had been issued increasing the number of elected managers by nine. Information as to the expenditure of the Asylums Board was already furnished by the managers to the guardians, and, prior to each half-yearly audit, the ledger accounts of the managers were open to the inspection of any ratepayer or owner of property in the metropolis.

Belfast Royal Hospital.

Mr. Sexton called attention to the claim of the Belfast Royal Hospital to a grant from the Treasury owing to the extraordinary demands made upon the institution as a result of the recent riots. The Chancellor of the Exchequer said that he would, in consultation with the Chief Secretary and the Attorney-General for Ireland, go carefully into the circumstances of the case; and if it were the opinion of the authorities in Ireland that a special grant should be made from the Treasury to this hospital on account of the expense it was put to in consequence of the riots, he, as Chancellor of the Exchequer, should throw no difficulty in the way of that being done.

On the 13th inst. Sir Michael Hicks-Beach, in reply to a further question from Mr. Sexton, stated that, as present advised, he did not think it would be right to recommend that Belfast and this hospital should be treated exceptionally by getting a Government grant for treating those injured in the riots. There might be a case for such a grant if the constabulary or military had been treated at the hospital, and he would inquire into this point.

The Pollution of the Thames.

In reply to Mr. Lawrence, who asked what steps the Metropolitan Board of Works were taking to remedy the nuisance arising from the pollution of the river Thames by the main drainage outfalls, Mr. Matthews stated that he could not, within the compass of an answer to a question, detail the scientific processes which were being carried out, and which would, it was confidently believed, be found sufficient to prevent the pollution of the river.

Proficiency Certificates in Vaccination.

On the 10th inst., Mr. Ritchie, in reply to Dr. Tanner, stated that the certificates of proficiency in vaccination required as part of the qualification for the appointment of public vaccinator in England could only be obtained at certain educational vaccination stations, which were subject to the inspection of the Local Government Board. Twenty public vaccinators in Great Britain had been authorised to grant such certificates; the stations being at London, Birmingham, Bristol, Exeter, Leeds, Liverpool, Manchester, Newcastle, Sheffield, Edinburgh, and Glasgow. The Board had in the present year been applied to to authorise the grant of such certificates at Dublin, and had expressed their willingness to do so upon certain arrangements being made in order to assimilate the practice with regard to the issue of certificates throughout the United Kingdom. Steps were now being taken for this purpose.

Later in the evening, during the consideration of the Civil Service Estimates, on the vote to complete a certain sum for the Local Government Board, Mr. A. O'Connor, after protesting against the practice of vaccination as inimical to the welfare of the community, proposed to move the reduction of the vote by the sum of £16,500, the amount appropriated in the vote to the payment of vaccination officers. After some remarks by Mr. Ritchie, Dr. Tanner, and others, the amendment was negatived without a division.

The Lunacy Laws.

On the 13th inst., in answer to Mr. Corbet, Mr. Matthews confirmed the previously announced intention of the Government to proceed with legislation on the subject of lunacy. It would be a matter for consideration whether this legislation should extend to Ireland and Scotland.

House-boats.

On Thursday, in reply to Mr. H. S. Wright Mr. Ritchie said the Thames Conservators were empowered under an Act of last year to make regulations for the prevention of the pollution of the river by steam launches or house-boats. They had prepared a bye-law which would render liable to a penalty any person who polluted the river by dropping into it offensive matter. This bye-law, with others, had received the approval of the Queen in Council. In answer to another question by Mr. Wright, the Chancellor of the Exchequer replied that house-boats on the river were not liable to Imperial taxation, and it was not proposed to impose any tax upon them, because the amount which would be collected would be insignificant. Under the bye-laws of the Thames Conservancy, however, it was intended to charge registration fees for house-boats.

SANITARY CONGRESS.—The annual Congress of the Sanitary Institute of Great Britain will be held this year at York under circumstances promising well for its success. The President of the Congress, which will open on the 21st inst., is Sir T. Spencer Wells, and the list of Vice-Presidents includes the names of Dr. Richardson, Dr. G. Buchanan, Sir J. Fayrer, Miss Nightingale, and Professor Humphry, of Cambridge. Sir T. Spencer Wells will give an address, and the sections, which are only three in number, will be—first, under Dr. De Chaumont, "Sanitary Science and Preventive Medicine"; second, under Mr. Baldwin Latham, assisted by Mr. E. C. Robins, "Engineering and Architecture"; and, third, under Mr. W. Whitaker, assisted by Mr. G. J. Symons, "Chemistry, Meteorology, and Geology."

Obituary.

ROBERT FOWLER, M.D., M.R.C.P. ED., M.R.C.S. ENG., &c.

ON August 7th there passed away from the medical profession in London Dr. Robert Fowler, of Old Burlington-street, W., and of Bishopsgate-street, City. Born in Belvidere-road, Lambeth, in the year 1828, and educated first at Merchant Taylors' School and then at the Grammar School, Cardigan, under the present Archdeacon Griffiths of Llandaff, Dr. Fowler was, on leaving school, placed as an apprentice with the late W. M. Noot, Surgeon, of Cardigan. Completing his apprenticeship, he entered as a medical student at King's College Hospital. Here, after due course, he obtained the Associateship of the College, and qualified M.R.C.S. and L.S.A. He then proceeded to Edinburgh University, where in the year 1851 he graduated M.D. After leaving Edinburgh he accepted the post of house-surgeon at Loughborough Infirmary; but after honourably fulfilling the duties for a time he left the infirmary and came to London. Settling in Bishopsgate, City, in the year 1854, although he was then but twenty-six years of age, he soon acquired an extensive and lucrative practice. For many years he held the post of medical officer to the East London Union; but, on the amalgamation of the three Unions into the combined City of London Union, he retired on a pension. Elected soon after a guardian of this union, he held his seat on the board till his death. He always took great interest in Poor-law medical relief, and at one time wrote extensively on the whole subject of Poor-law medical reform. He gave extensive evidence before the Commons' Select Committee on Poor-law Relief, and by so doing he was very materially instrumental in the passing of Hardy's Act. In 1879 he was elected by the City of London Union one of their managers on the Metropolitan Asylums Board. Here he soon distinguished himself for useful work, and on the occasion of the recent scandals in the management of the Homerton Fever Hospital he was very active in promoting the inquiry. Eleven years ago he was elected an examiner of the Society of Apothecaries, and, with the exception of one year, was re-elected every year since. For some time he held the post of librarian to the Hunterian Society, and to him the Society are indebted for the catalogue of their library. In the year 1882 he was selected the Society's Orator, and the oration which he delivered was so able and interesting that, in deference to a widespread request, it was afterwards published in the form of a pamphlet. The title of the oration is, "The Attributes, Professional and Social, of the so-called 'Family Doctor,'" and the author of it was so highly esteemed by the members of the Society that the following year he was elected their president.

Dr. Fowler was so active and industrious, and so desirous of doing good, that during the whole of his career he never allowed any opportunity to pass of performing a public service. In 1870, by a long letter to *The Times*, he drew attention to the celebrated case of the Welsh Fasting Girl, and having made himself thoroughly acquainted with every detail, he published a comprehensive volume on the whole case. The full title of the work is, "A Complete History of the Welsh Fasting Girl, with comments thereon; and observations on Death from Starvation." The work is chiefly interesting to the practitioner of medicine on account of its scientific worth—that is to say, by reason of Dr. Fowler's discussion of the subject of starvation in general; but even to the ordinary reader his remarks are so clear and obvious, that few such persons taking up the work would omit to read his observations on death from starvation.

Dr. Fowler was the author of a Medical Vocabulary, a work which has already reached a second edition. The task, however, will be in due time taken up and completed by his son. In addition to his ordinary literary work, he at one time tried his hand at poetry; and the amusing poem headed "The Parish Leech," and published some years ago under the *nom de plume* of "A Parish Doctor," was really from his pen. His contributions to the medical journals were varied and numerous, and for a long series of years he was an occasional contributor to the columns of this journal. His last literary effort was an interesting illustrated article entitled "On the Discovery of one of the 'Seites' set apart in Whitechapel for a Pest-ground, *temp.* Edward III.," which was published in THE LANCET about a year ago, and afterwards republished in pamphlet form.

CHARLES CHADWICK, M.D., F.R.C.P. LOND.

DR. CHADWICK, whose death occurred somewhat suddenly at Buxton on the 30th ult., was born at Leeds in 1815. He received the major part of his medical education in Edinburgh, and in 1837 took the degree of Doctor of Medicine at the University of that city, becoming a Fellow of the Royal College of Physicians of Edinburgh in 1845, and a Fellow of the Royal College of Physicians of London in 1866. Settling down to practice in his native town, Dr. Chadwick soon attracted attention, and whilst comparatively young was elected physician to the Leeds General Infirmary, an office which he retained for nearly eight years. At the same time he held various lectureships in connexion with the Leeds School of Medicine, an institution in whose welfare and prosperity he took a lively and active interest. To Dr. Chadwick's exertions, too, Leeds is mainly indebted for the hospital which at the present time adorns the town. In the West Riding Medical Charitable Society Dr. Chadwick took a great interest, and of it he was for many years the chief director. He found no labour too great to bestow upon it, and he contributed largely to its funds in money, as well as in time and labour; and when, in consequence of failing health, he was compelled to retire from its active management, the members, in recognition of his services and as a token of their regard, presented him with a substantial gift of silver plate. Dr. Chadwick was president of the British Medical Association in 1869, when the annual meeting was held in Leeds, and afterwards became a vice-president of that body. He was a Justice of the Peace for both the borough of Leeds and for the West Riding of the county of York, and he was also one of the twenty-five patrons of the parish church of Leeds. Some twelve years ago, when removal from Leeds was necessitated by failing health, he took up his residence at Tunbridge Wells, and, although he was known to be suffering from diabetes, the news of his death came upon his friends as a surprise, as in a recent visit to the north of England he manifested a degree of robustness which encouraged the hope that his life might have been prolonged for some time.

Medical News.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on Thursday, the 2nd inst.:—

Gibbon, Ernest Henry, Marlborough House, Seaham.
Gillmon, John Charles, Oxonian-street, East Dulwich Grove.
Gregory, Seth, Birchanger-road, South Norwood.
Hughes, Hugh Lewis, Bridge-street, Llanbadarn, Aberystwyth.
Todd, Henry, Mile-end-road.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Goodwin, William Henry Frederic, Westminster Hospital.
Lewington, John Joseph, London Hospital.
McGeagh, William Stewart, St. Thomas's Hospital.

The following gentlemen passed and received certificates to practise, on Thursday, the 9th inst.:—

Brooks, Richard Philip, Tollington-park.
Griffiths, William, St. John's Wood Terrace.
Marks, Robert John, Canyage-square, Clifton, Bristol.
Melland, Brian, Victoria-park, Manchester.
Rusher, John Golby, Pershore, Worcestershire.
Wright, Charles Franklin, Trafalgar-road, Great Yarmouth.

THE annual sermons on behalf of the local infirmary were preached at Bridgwater on the 12th inst.

THE Municipal Council of Milan has contributed the sum of £400 to the Pasteur International Institute.

THE Sanitary Committee of the Bolton Corporation have decided to invite the members of the Sanitary Institute to hold their annual congress at Bolton next year.

AT a meeting of the City Commission of Sewers on the 14th inst., Dr. Sedgwick Saunders, the medical officer of health, stated that the deplorable state of the river Thames near Purfleet arose through the experiments in deodorising sewage now being made by the Metropolitan Board of Works, which experiments, in his opinion, were worse than useless, and were only serving to lull the public into false security. Some eight million gallons of sewage out of the 160 millions daily discharged into the river are being experimented on at, it is reported, a cost of £3000 per week.

THE MAYORALTY OF WOLVERHAMPTON for the ensuing jubilee year has been offered by resolution of the Borough Council to Mr. Vincent Jackson, F.R.C.S.E., surgeon to the Staffordshire General Hospital, who has written to the present Mayor accepting the nomination.

SHEFFIELD SCHOOL OF MEDICINE.—The Winter Session 1886-7 will commence on Friday, October 1st, at 5 P.M., when the introductory lecture will be delivered in Firth College by Dr. W. S. Porter, physician to the Public Hospital and Dispensary and lecturer on Physiology. The prospectus and all information may be obtained from Arthur Jackson, secretary.

A PARKES MUSEUM FOR PARIS.—The Paris Municipal Council have decided to open a Hygienic Museum, in which the microscopic effects of allowing water to stagnate, the skin to remain dirty, and bad air on the blood will be shown, as well as other causes of disease. Lectures on the laws of health will be delivered in connexion with the exhibition.

BUTTER SUBSTITUTES.—The Bill to amend the law relating to the trade in butter substitutes, brought into the House of Commons by Sir Joseph McKenna, imposes a maximum penalty of £20, or one month's imprisonment, on any person importing, manufacturing, or offering for sale, margarine or oleomargarine without due branding of the name on all packages. The penalty is increased to £50, or six months' imprisonment, for a second offence. Margarine or oleomargarine factories are to be registered and inspected.

PRESENTATION.—At the half-yearly meeting of the governors of the Wolverhampton and Staffordshire Hospital on the 14th inst., Dr. Millington, who until recently held the position of senior honorary physician, was presented with a life-size portrait of himself, painted in oil, a silver salver, and tea and coffee service, in testimony of the valuable services he had rendered to the institution for the long period of thirty-two years. It has been arranged that the portrait shall be hung in the board-room of the hospital.

THE DISPOSAL OF TOWN REFUSE.—On the 14th inst. the members of the Preston Town Council inspected a refuse destructor which has just been erected in that town at a cost of £6387 exclusive of the site, the purchase-money of which was £12,000. The destructor consists of eight furnaces, each of which will consume seven tons of refuse in twenty-four hours. The furnaces have been in operation a few days, and the inspection was considered to be perfectly satisfactory.

NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—At the monthly meeting of the members of this Association on the 9th inst., Dr. Vacher, the medical officer of health for Birkenhead, read a paper entitled "When Infectiousness begins and when it ends in Scarlatina, Measles, Small-pox, Mumps, and Diphtheria." With regard to the first point, Dr. Vacher pointed out that there was danger from infection from the moment the patient became infected, and, as to the time when the infectiousness terminated, that this was determined by the time it took for the complete elimination of the morbid products thrown off by the patients.

PARKES MUSEUM.—During next month the following lectures and demonstrations will be delivered at Margaret-street, Regent-street:—October 4th: Introductory lecture on General History, Principles and Methods of Hygiene, by Dr. G. V. Poore. 6th: Water-supply, Drinking-water, and Pollution of Water, by Professor Corfield. 8th: Drainage-construction, by Professor H. Robinson. 11th: Sanitary Appliances, by Mr. Gordon Smith. 13th: Ventilation, Measurement of Cubic Space, &c, by Professor F. De Chaumont. 15th: Scavenging and Disposal of Refuse, by Mr. Percy Boulnois. 18th: Food (good and bad), Milk, Sale of Food and Drugs Act, by Mr. C. E. Cassal. 20th: Infectious Diseases and Methods of Disinfection, by Dr. R. Thorne Thorne. 22nd: General Powers and Duties of Inspectors of Nuisances (Method of Inspection), by Mr. J. F. J. Sykes. 25th: Nature of Nuisances, including Nuisances the abatement of which is difficult, by Mr. J. F. J. Sykes. 27th: Sanitary Law—General Enactments, Public Health Act, 1875, Model Bye-laws, by Dr. Charles Kelly. 29th: Metropolitan Acts, Bye-laws of Metropolitan Board of Works, by Mr. A. Wynter Blyth.

BRIDGE-END ASYLUM.—At the meeting of the Merthyr Board of Guardians on the 11th inst. attention was called to the fact that, although the majority of the 800 patients at the county asylum at Bridge-end were Welsh, and a number of these were unable to understand English, none of the medical officers understood Welsh. Owing to this circumstance, it was hinted that patients remained longer in the institution than was necessary, and it was unanimously resolved, in view of the erection of a new asylum building at a cost of £100,000, that it is desirable that officials conversant with both the English and Welsh languages be engaged.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

COTTERELL, EDWARD, M.R.C.S., L.R.C.P.Lond., has been appointed Medical Officer to the Stoke Lyne District of the Bicester Union.

EVANS, C. W., M.B.Lond., M.R.C.S., has been appointed Visiting Medical Officer to the Bakewell Union Workhouse, vice Chas. Evans, deceased; and Certifying Surgeon, under Factories and Workshops Act, for Bakewell District.

FERRIER, DAVID, M.D., F.R.S., Professor and Physician at King's College Hospital and the National Hospital for the Paralysed and Epileptic, has been appointed Physician to the British Home for Incurables, Clapham.

KINGDON, E. C., M.B., C.M.Edin., late Assistant Medical Officer to the Middlesex County Asylum at Colney Hatch, has been appointed Assistant House-Surgeon to the General Hospital, Nottingham.

LOWRY, J. H., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer, Imperial Maritime Customs, Pakhoi, China, has been appointed Medical Officer, Imperial Maritime Customs, Kiungchow, Hainan, China, vice Dr. E. A. Aldridge, transferred to Wuku.

PAGET, CHARLES E., M.R.C.S., L.R.C.P.Lond., has been reappointed Medical Officer of Health for the Westmoreland Combined Sanitary District, for a second term of three years.

PAYNE, WILLIAM ARTHUR, B.A.Oxon., M.R.C.S., L.S.A., has been elected House-Surgeon to the Richmond Hospital, Surrey, vice John Williamson, M.B., resigned.

SMITH, PATRICK BLAIKIE, M.D., C.M.Aber., has been appointed Assistant Physician to the Aberdeen Royal Infirmary.

SWANN, ALFRED, M.D., M.R.C.S., &c., has been appointed Certifying Factory Surgeon for the Batley District, vice Stockwell, deceased.

TROUTON, GARDINER, M.B., B.Ch.Univ.Dub., has been appointed House-Surgeon to the Cumberland Infirmary, vice G. Francis Smith, M.R.C.S., L.R.C.P., resigned.

WILLIAMS-FREEMAN, JOHN P., M.B.Dur., M.R.C.S., L.S.A., has been appointed House-Surgeon to the Royal Portsmouth, Portsea, and Gosport Hospital.

Births, Marriages, and Deaths.

BIRTHS.

BOSWELL.—At Saffron Walden, Essex, the wife of Henry St. George Boswell, M.B., C.M., of a daughter.

BROCK.—On July 7th, at Urlar, Rouxville, Orange Free State, the wife of George Sandison Brock, M.B.Ed., C.M., of a son.

CANE.—On the 7th inst., at The Gables, Belvedere, Kent, the wife of Howard Cane, M.D., L.R.C.P.Lond., of a son.

DONALD.—On the 28th ult., at Ambleside-avenue, Streatham, S.W., the wife of David Donald, M.D., C.M., of a daughter.

EDGAR.—On the 5th inst., at Settle, the wife of James W. Edgar, M.D. (prematurely), of a son.

FINLAY.—On the 3rd inst., at Lower Berkeley-street, Portman-square, W., the wife of David W. Finlay, M.D., F.R.C.P., of a daughter.

GALLOWAY.—On the 4th inst., at Epping, the wife of Arthur Wilton Galloway, M.R.C.S., L.R.C.P.Lond., of a son.

MURPHY.—On the 7th inst., at Holly House, Sunderland, the wife of Dr. Murphy, of a daughter.

NORRY.—On the 3rd inst., at Telford-park, Streatham-hill, S.W., the wife of William Augustus Norry, M.B., M.R.C.S., of a daughter.

OLIVER.—On the 8th inst., at Consett Hall, co. Durham, the wife of Thomas Oliver, M.D., of Eldon-square, Newcastle-upon-Tyne, of a son.

OWEN.—On the 11th inst., at Wattham's Dene, Twyford, Berks, the wife of Owen Owen, Brigade-Surgeon, retired, of a daughter.

POTTS.—On the 12th inst., at Vicarage-villas, Willesden, N.W., the wife of W. A. Beevor Potts, M.R.C.S., L.S.A., of a daughter.

SHANN.—On the 6th inst., at Micklegate, York, the wife of Henry Chas. Shann, M.R.C.S., of a son.

SHAPTER.—On the 7th inst., at Barnfield-crescent, Exeter, the wife of Lewis Shapter, M.D., of a son.

SPENCER.—On the 12th inst., at Albion-road, Stoke Newington, the wife of E. R. Spencer, M.R.C.S., L.R.C.P., of a son.

STOKES.—On the 8th inst., at Rose Park Lodge, Upper Tooting, S.W., the wife of F. A. Stokes, L.R.C.P., M.R.C.S., of twins (boys).

WALKER.—On the 10th inst., at Hurworth-on-Tees, the wife of Charles Edward Walker, M.B., M.R.C.S., of a son.

WORNUM.—On the 13th inst., at 6, College-terrace, Belsize-park, Hampstead, N.W., the wife of George Porter Wornum, M.R.C.S.Eng., of a daughter.

MARRIAGES.

BULL—GARDE.—On the 7th inst., at St. Mary's, Shenley Mansel, by the Rev. John Wood, Vicar of Old Wolverton (Rural Dean), William H. Bull, F.R.C.S., of St. Oswald's House, Stony Stratford, second son of W. J. Bull, Solicitor, of Oswestry, to Emma B. Cherry Garde, youngest daughter of the late Edward Hoare Garde, Esq., of Balunascurra House, co. Cork, and sister of the Rev. J. H. Garde, Rector of Shenley Mansel, Bucks.

CAMPBELL—HIRST.—On the 9th inst., at St. Chad's, Saddleworth, Colin George Campbell, M.R.C.S., of Uppermill, Saddleworth, to Annie Ethel, only daughter of Ben Hirst, of Tamewater House, Saddleworth, Yorkshire.

COLLINS—COPELAND.—At St. Mary's Church, West Rainton, by the Ven. Archdeacon of Durham, assisted by the Rev. Hugh McNeile Minton-Senhouse, M.A., brother-in-law of the bride, Surgeon M. J. Collins, R.W.I.M.S., eldest son of the late M. J. Collins, Solicitor, of Cork, to Esther, fourth daughter of the Rev. G. D. Copeland, B.D., Rector of W. Rainton, Durham.

DAVISON—VIVANCO.—On July 24th, at St. John's Church, Buenos Ayres, by the Right Rev. the Bishop of the Falklands, assisted by the Rev. Austin West, M.A., Rector of St. John's, and by the Rev. Lennox Robertson, M.A., James Thomas Richard Davison, M.D., youngest son of the late Robert Davison, Esq., of Monte Video, to Ernestine, fourth daughter of Hilarion Vivanco, Esq., of Tigre.

GREENSILL—BRETTELL.—On the 9th inst., at the Parish Church, Dudley, James Heynes Greensill, M.R.C.S., L.S.A., of Parkstone, Dorset, to Ellen Blanche Brettell, eldest daughter of Thomas Brettell, of Dudley.

HALLIBURTON—DAWE.—On the 2nd inst., at All Saints, Gordon-square, W.C., by the Rev. E. G. Hall, W. D. Halliburton, M.D., to Annie, daughter of James Dawe, of Antony, Cornwall. No cards.

JOHNSON—WELCH.—On the 31st ult., at St. George's, Kidderminster, Thomas Johnson, M.R.C.S., L.R.C.P., to Beatrice, youngest daughter of John Welch, of Kidderminster.

JOSHUA—MURRAY.—On the 9th inst., at St. James' Episcopal Church, Dollar, by the Rev. H. E. Maskew, the incumbent, Francis William Joshua, L.R.C.P., L.R.C.S.I., of Great Malvern, son of William Joshua, F.L.S., of Cirencester, to Elizabeth Agnes Murray, of Dallarbeg, Dollar, eldest daughter of the late John Edwards Murray, sometime of Quartertown-park, Mallow and Rock Lodge, Youghal, co. Cork.

KELLIE—DUNLOP.—At Southfield, Dunbar, by the Rev. R. Buchanan, Geo. Jerome Kellie, Surgeon, 4th Regiment of Cavalry, Hyderabad Contingent, to Eliza Catherine, third daughter of the late Dr. Jas. Dunlop, of Abbey Lands, Dunbar.

MORRIS—NUTT.—On the 4th inst., at Emmanuel Church, West Dulwich, Clarke Kelly Morris, M.R.C.S.E., L.S.A., of Blackheath, son of Edwin Morris, M.D., F.R.C.S., of Spalding, to Mabel Josephine, daughter of the late D. Nutt, of 270, Strand, and stepdaughter of the late D. W. Logie, of Rosendale Hall, West Dulwich.

NOAKES—ASHMORE.—On the 8th inst., at All Saints, Margaret-street, by the Rev. A. J. Noakes, brother of the bridegroom, S. S. Ashmore Noakes, L.R.C.P., M.R.C.S., of Nice, and St. Winifred's, Windsor, to Harriette Paley, eldest daughter of the late Major Ashmore, 16th Regiment, of Bath.

TURNER—MCDOUGALL.—On the 7th inst., at St. Mary Abbot's, Kensington, Francis Charlewood Turner, M.D., to Mary Colenso McDougall.

WALKER—BRIDGE.—On the 2nd inst., at the Parish Church of St. John, Clapham-rise, Charles Rotherham Walker, M.D., to Lillia Gertrude Mary, third daughter of the late Alexander Bridge, M.D., F.R.C.S., of Argyll-place, W.

WALLACE—VACHELL.—On the 9th inst., at St. Andrew's Church, Bath, Samuel Wallace, L.R.C.P.Ed., L.R.C.S.Ed., of Cardiff, to Emily Harriett, youngest daughter of the late Dr. Vachell, of Cardiff.

WELLER—SEVERNE.—On the 2nd inst., at Dringhouses, York, Charles Joseph Weller, M.R.C.S., L.R.C.P.Lond., to Ellen Frances Louisa, daughter of Captain Severne, late of Dringhouses.

DEATHS.

BAIN.—On the 31st ult., at Brighton, Alexander Gordon Bain, R.N., Surgeon (retired), aged 49.

GRANGER.—On the 11th inst., at his residence, Alveston Lodge, Durdham Down, Bristol, Frederic Granger, M.R.C.S., L.S.A., in his 89th year.

HOLL.—On the 11th inst., at his residence, Derby-villas, Cheltenham, Harvey Buchanan Holl, M.D., M.R.C.S., aged 65.

JELLY.—On the 14th inst., at Buxton (suddenly), Fred. A. Jelly, M.B., C.M., the beloved son of Wm. Jelly, M.D., F.R.C.P.Lond., late of Valencia, Spain, aged 29.

LEWIS.—On the 13th inst., at Loughton, Essex, William Thomas Lewis, M.R.C.S.Eng., L.S.A., in his 58th year.

MILLER.—On the 31st ult., at Beaumont-villas, Spring-grove, Isleworth, George Miller, M.D., formerly of Emsworth, Hants, and Sidmouth, Devon, in the 76th year of his age.

MOINET.—On the 6th inst., at Edinburgh, Francis Walter Moinet, M.D., F.R.C.P.E.

STEPHEN.—On the 11th inst., at Carlsbad (of cholerina), William H. G. Stephen, M.B., C.M.Edin., L.R.C.P.Lond., youngest son of the late William Stephen, of Inchbroom, Morayshire, aged 24.

THORNTON.—On the 7th inst., at Hinxton Grange, Saffron Walden, Eleanor Philippa, the beloved wife of J. Knowsley Thornton, M.B., C.M., of 22, Portman-street, London, W.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

THE HOSPITAL FOR WOMEN AT LIVERPOOL AND THE NEWSPAPERS.

OUR opinion is asked as to the propriety of medical men carrying on controversies on medical matters in the daily papers. As a rule, the practice is one to be deprecated most strongly. In this particular case, however, it must be admitted that there is some excuse for a departure from the rule. The questions involved have been made public; they have been tried in a court of law. The interest of the hospital, too, and its management are involved by the publicity given to statements in the course of the trial. Any attempt to suppress newspaper discussion would be misconstrued, and would operate adversely on the hospital. Undoubtedly, the sooner medical men withdraw from the newspaper discussions of these topics the better, provided the public is assured that sound rules of professional conduct are laid down, and security has been taken for their being well observed. Voluntary hospitals would collapse without such precautions.

W. V., L.R.C.P.E.—Our correspondent cannot now register without obtaining a diploma. The last day for registration on the ground of "being in practice before the passing of the Act" expired on July 31st, 1879. There is one exception to this rule—viz., if a person was apprenticed to a dental practitioner and paid a premium prior to the passing of the Act he is still permitted to register as a dentist.

Mr. Robert Hamilton.—Dr. Diver's book, "A Young Doctor's Future," published by Smith, Elder and Co., might be of service.

Rodney should apply to some such firm as Moore and Co., 125, Houndsditch.

"TREATMENT OF STOMATITIS."

To the Editor of THE LANCET.

SIR,—In response to your correspondent, "M.B.," regarding the treatment of stomatitis, I should suggest the following, which I have never found to fail with cases that have come under my notice. First have recourse to mel boracis, to which add a little pot. chlor., and paint the affected parts with a camel-hair pencil three or four times a day. Should the above not suffice, after a fair trial use the sulphurous acid together with the above, which may also be applied with a camel-hair pencil. However, I think the better plan is to use the acid with a spray, because the affected parts are more easily reached in that manner. Be most particular about the diet, and give some mild tonic, to which add pot. chlor. I have every reason to believe that if the above is carried out, the result will be found most satisfactory.

I am, Sir, yours truly,

Aug. 30th, 1886. M.D.

TOUTING FOR PRACTICE IN NORTH LONDON.

M.B.Edin. sends us two bad specimens of touting. One in the form of a visiting card left at the house of a patient of our correspondent, and having on it, "Dr. T——, Surgeon and Accoucheur, Willoughby House, Willoughby-road," and said to have been left at the other houses in the road. The other a handbill announcing the opening of a practice at Andover House, Devonshire-road, Holloway, by a registered physician, surgeon, and accoucheur; fees charged strictly moderate for cash, &c. Really, this is too bad. What are our corporations about to allow such practices by their licentiates? Our correspondent should forward the documents he sends us to the bodies from which these parties obtained their diplomas.

M.A. & D.D. will see by our answer to other correspondents that we have resolved not to continue at present the discussion on the recognition of foreign degrees. That some such degrees must be recognised is clear; but whether "useful work among the poor," any more than among the rich, will be done by men with low degrees we very much doubt.

Mr. M. R. Edwards.—We have no knowledge of any such society as that mentioned.

Mr. Bedford Fenwick.—The paper is marked for insertion.

Dr. Arthur H. N. Lewers.—Yes.

"UNQUALIFIED ASSISTANTS."

To the Editor of THE LANCET.

SIR,—I have read with interest a letter in your issue of the 4th inst. in reference to the employment of unqualified persons as assistants and locum tenens. A great deal has been written on the subject, without, I regret to say, so far, making any apparent change in such a decided abuse. That the system of employing unqualified assistants is extensively carried on not alone in the Midland counties, but throughout England, I have had ample and varied opportunities of knowing. I am at present engaged, and have been from time to time for nearly three years in different parts of England, as locum tenens, and have also held two or three assistantships. I am therefore in a position to give some information as regards the abuse complained of. One or two instances of my experience may perhaps be of interest.

Shortly after I qualified I sought an engagement as assistant, and was engaged to take charge of a branch practice in London. At this branch was an unqualified person, who had had the management of the practice for four or five years, with only an occasional visit from the principal. When I entered on my engagement it was arranged that this unqualified man and I were to live together. I was led to expect that he would attend to such duties as dispensing, &c.—duties fitted for an unqualified person. I soon learned, however, that I was only nominally in charge of the practice; that this ignoramus was really the person invested with the management of it, and that I was, so to speak, his assistant. His salary was double that which I received; he was looked upon by the patients and general public as the owner of the practice, and was usually addressed as "Dr. ——." Of course, I was looked down on as nobody, and on one or two occasions he even consulted with a qualified practitioner, this gentleman being under the impression that he was consulting with Dr. ——. Having for a time submitted to this state of things, I gave this unqualified person to understand that I would not submit any longer. This elicited some hot words, with the result that I had an interview with the principal, in which I informed him that either his reliable unqualified deputy or I should leave. The principal having evinced an unwillingness to part with this distinguished representative of unqualified practitioners, I accordingly decided to leave, and left in a few days without the usual month's notice. I know of many other cases in which unqualified assistants are employed, and entrusted with the lives of hundreds of people, the principal only putting in an occasional appearance—once a week, or perhaps not so often. The generality of unqualified assistants have never been inside a hospital, can scarcely tell the heart from the liver, and have not even passed a preliminary examination. On the other hand, there are a few unqualified assistants (they are, indeed, "few and far between") who have taken out all their lectures and hospital practice, and have been really hard-working students, but are through pecuniary difficulties unable to qualify.

I am, Sir, your obedient servant,

Bath, Sept. 6th, 1886. JAMES J. O'BRYEN, M.D.

MECHANICS AT THE PRELIMINARY EXAMINATION.—A CORRECTION.

IN the answer addressed to "Student" in our issue of the 4th inst., p. 477, the date of the regulation of the General Medical Council respecting the above should have been given as Oct. 1st, *1885*, not 1886.

P. Q. Y.—Certainly so. No qualification is required to enforce a midwifery charge. Even a midwife is worthy of her hire—much more a member of the English College of Surgeons.

Mr. A. De St. Dalmas.—It would be premature to express an opinion of the merits of the invention until some experience has been gained of its utility.

A. P. S.—The question has been repeatedly answered in our columns—e.g., THE LANCET, March 13th, 1875, and July 14th, 1883.

Meg.—Yes, shortly.

A PRESCRIPTION BOOK OF THE ELEVENTH CENTURY.

MEDICINE has her archæology like every other learned vocation, and hardly a year passes without adding to her treasure-trove. In one of the precious MSS. contained in the Capitular archives of Ivrea, in Piedmont, Prof. Piero Giacosa has found a book of receipts which remounts to the eleventh century. The professor discourses learnedly on this book, pointing out, amid the scarcity of medical writings at that remote date, the importance of a document which adds to the proofs—authentic, if rare—that the ancient Græco-Latin tradition of medicine was still preserved, and that it may have given origin, without the intervention of Arabian medicine, to the famous school of Salerno. The MS. in which the book is inserted belonged to Warmund, Bishop of Ivrea, famous even in the first years of the stormy eleventh century for his love of science and literature. Before the prescriptions comes a group of receipts for writing with gold, for making gold ink, and for illuminating parchment. Then follows a catalogue of maladies, thirty-two in number, more than half of them relating to the eyes, while the remainder have reference to the head, the ears, the throat, the kidneys, and so forth. Each malady has its remedy—one or more,—the majority belonging to the vegetable kingdom, though the animal world supplies not a few. Among the latter we have fat of eels, raw flesh, the gall of a great variety of animals, such as the eagle, the cock, the hyæna, the hare; then goat's dung, hartshorn, serpents' skins, worms, &c. The vegetable remedies include aloes, camphor, cassia, lettuce, honey, opium, sundry aromatic herbs, rue, linseed, mustard, and so on. Finally come a few chemical and inorganic remedies: orpiment, lime, nitre, sulphur, French soap, &c. According to Prof. Giacosa the medicines are mostly derived from Dioscorides and Pliny. He also finds a correspondence, in the matter of arrangement, between the prescription book of Ivrea and the work of Lucius Apulelus Platonicus on the virtues of herbs—a work of which the compiler of the prescription book availed himself as a guide, and of which the Chapter of Ivrea doubtless possessed a copy now lost. The original part of the prescription book betrays a scientific turn of mind in advance of the age as to the conception of disease and the *modus operandi* of remedies. The author signs himself "Petrus Magrus"—probably a fictitious name, it having been the frequent habit of early mediæval writers on medicine to assume the surname "magrus" (lean), an epithet, according to Prof. Giacosa, which implies a not very lucrative practice. The importance of the professor's discovery, as we have said, lies in its demonstration that in Italy the Græco-Latin tradition in medicine was never lost. In fact, in the Ivrea MS. there is mention of but one remedy due to the Arabs—to wit, camphor. This drug, isolated among the others, proves that while in the eleventh century the Arabian pharmacopœia was not unknown, it had not yet, as a whole, taken root in Italy.

M.B.Lond.—The subject being newly introduced into the examination its scope is not sufficiently defined to warrant the giving of precise advice as to reading. Carpenter's "Mental Physiology" and Maudsley's "Physiology of the Mind" are works of considerable reputation, and would probably be useful.

E. C.—We do not give medical advice.

CHOREA AND ITS TREATMENT.

To the Editor of THE LANCET.

SIR,—I am looking anxiously for some comment, by someone better able than myself to judge, upon the treatment of the case of acute chorea in St. Vincent's Hospital, Dublin, reported in your issue of Sept. 4th. A child of ten years of age was given sulphate of zinc for fourteen days, in doses which gradually increased to thirty grains four times daily, together with a nightly draught of ten grains of chloral and thirty grains of bromide of potassium. On the ninth day considerable epistaxis and paralysis of the sphincters of the bladder and anus occurred. The circulation gradually failed through the succeeding days, and death took place on the fifteenth day.

I am, Sir, yours obediently,

September, 1886. A GENERAL PRACTITIONER.

DISPUTE AT TREHERBERT.

WE cannot undertake to give any opinion on such a serious and complicated dispute as this on the strength of an entirely one-sided statement. Our correspondent would do well to seek the judgment of a third party on the spot, before whom all facts could be laid.

Sigma.—It is not usual for a house-surgeon to be allowed beer money. In most cases he is provided with sufficient alcoholic beverages, and where this is not done he has to provide himself with them at his own cost. In one hospital, we believe, there is an allowance of a shilling a day, but this is exceptional. The question suggests too much the idea of bargaining with servants as to their "allowance."

A Constant Reader.—The question is a legal one, and we cannot speak positively; but we think our correspondent has a claim on the guardians or the relieving officer.

Digitized by Google

THE RECOGNITION OF FOREIGN DEGREES.

M.D., Nemo, M.D. New York, &c.—We must believe that the Medical Council will be careful in the degrees which it recognises. Our correspondent "M.D." does not say what university it is that requires seven years' study of medicine. The profession must make due representations to the Medical Council when it enters on the grave duty of recognising foreign degrees. Such letters as that of "Nemo" will be more useful later on, especially if shorter. The discussion on the recognition of American degrees and their value must for the present close.

H. J. W.—We cannot at the moment indicate a book which would quite fulfil the requirements of our correspondent; but Cassell's Domestic Medicine might answer the purpose.

Mr. J. W. Orr should consult Mr. Henry C. Burdett's book on Cottage Hospitals.

"THE MEDICAL REGISTER."

To the Editor of THE LANCET.

SIR,—With reference to the complaint of Dr. Britton *re* the Medical Register, surely it is time the profession refused to submit longer to the scandalous manner in which names are removed from the Register. Being about to travel, I sent a notification of the fact to the registrar, enclosing a stamped envelope for acknowledgment (as I was aware that the funds of the Medical Council did not admit of the expense incurred in acknowledging a communication from a registered practitioner). I received an acknowledgment, saying my (then) present address would be retained on the Register. I happened by chance to be in England when the circular referred to by Dr. Britton reached me, and I was able to reply to it. Now, Sir, if I had left England one week earlier, I conclude my name would have been removed from the Register, as, owing to my somewhat erratic movements, it would have been quite a chance whether the communication from the registrar had ever reached me, and I should have been absent from England probably twelve months. A qualified practitioner pays an exorbitant fee for the privilege of being registered, and receives the following benefits:—He helps to pay the Medical Council enormous fees for the time they waste in framing new rules and regulations for the profession at one meeting which they usually annul at the next. The names of registered practitioners are removed from the Register whenever, in accordance with the most arbitrary and ridiculous rule of the Council, the registrar can do so, whilst no steps whatever are taken to expose and stop the practice of numerous unregistered and unqualified persons who style themselves doctors, who impose on the public and bring great discredit on the profession. I am, Sir, your obedient servant,

Sept. 7th, 1886. REGISTERED.

Mr. H. Bedwell.—There is no evidence that we are aware of in favour of the belief.

IRON IN ENTERIC FEVER.

To the Editor of THE LANCET.

SIR,—On May 16th, 1884, you inserted a letter in your columns which referred to the value of iron in septicæmia. In the closing sentence of that communication I mentioned the use of that drug in the treatment of enteric fever. I have recently used the perchloride in five-drop doses in two cases of that disease, and have been much pleased with the result. The temperature fell to the normal in from eight to twelve days. The iron, sweetened with glycerine, was given every two hours. The diet was strictly a milk one. I am, Sir, yours truly,

Clayton-le-Moors, Aug. 26th, 1886. C. R. ILLINGWORTH, M.D.

M.B.—Has our correspondent considered that there are already two London candidates well to the front?

Mr. J. H. Bell.—THE LANCET, Nov. 3rd, 1883.

"THE USE OF COCAINE IN CIRCUMCISION."

To the Editor of THE LANCET.

SIR,—Dr. Hett's last letter reduces the controversy between us practically to two issues:—1. If there be no phimosis, is a redundant prepuce in the slightest degree prejudicial, either to the child or to the adult? 2. Is the compulsory cleanliness procured by its excision any sufficient warranty for the performance of circumcision? My own impressions lead me to answer both questions in the negative. Dr. Hett, of course, takes an opposite view; it is for others to judge which is right. It is sufficient for me to have pointed out that congenital phimosis can be easily remedied by a much simpler and safer procedure than the one now almost universally in vogue.—I am, Sir, yours faithfully,

Norfolk-terrace, W., Sept. 7th, 1886. HERBERT SNOW.

THE CONTAGIOUS DISEASES ACTS.

To the Editor of THE LANCET.

SIR,—May I be allowed to draw attention to the following words, spoken last week in the House of Commons by Lord C. Beresford:—"The large increase in the sick-list in the Navy was due to the abrogation of the Contagious Diseases Acts and to the campaign recently undertaken." It is quite refreshing to read such words coming from a man like Lord C. Beresford, and protesting as they do against the short-sighted legislation which removed the protection of these lists from our garrison towns and seaports.—I am, Sir, your obedient servant,

Charlotte-street, W., Sept. 13th, 1886. H. DE MÉRIC.

"SEPARATE" QUALIFICATIONS.

THE following circular, obviously for wide distribution, sets the subject of separate qualifications in a new light:—

"122, Southwark Park-road, S.E., August, 1886.

"Dr. Rugg presents his compliments to the inhabitants of this neighbourhood, and begs to inform them that he has commenced practice at the above address. Dr. Rugg holds *separate* diplomas in every branch of his profession—i.e., as a physician, surgeon, apothecary, and accoucheur. He has had a large experience of surgical cases, gained during the Franco-Prussian War, and later as medical officer in the Australian mercantile marine. He therefore hopes that by careful and conscientious attention to the duties of his profession, and by combining his mature experience with the most moderate charges, he may be enabled to gain the confidence and patronage of his neighbours. Dr. Rugg would further state that having received an extra degree in diseases peculiar to women and children, offers them special attention."

Then follows a tariff.

Enquirer.—Our advertising columns contain all the information we have upon the subject.

Dr. H. Snow's paper will appear shortly.

"A NEW AND IMPROVED CLAMP FOR HÆMORRHOIDS."

To the Editor of THE LANCET.

SIR,—Returning from a happy little holiday, I regret to find I have given pain to Mr. Benham; He should bear in mind that when we offer anything to the profession, as both he and I have done with our clamps, we must be prepared to accept criticism, even though it be adverse. In my own practice I have had every reason to be satisfied with the instrument which I devised for myself in preference to his, and even Mr. Allingham's. Practically my instrument proves perfectly efficient and reliable. Mr. Benham's experiment at the maker's was made with an imperfect and rejected clamp—rejected for the reason that it permitted play between the collar and shaft. A perfect instrument was shown by me when I read a paper at the recent meeting of the British Medical Association here, and it met with a reception quite satisfactory to

Yours faithfully,

Brighton, September, 1886. CHARLES J. SMITH.

Scalpel.—Our last week's issue contains the information required.

Mr C. H. Eyles.—Soon.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

Lectures
ON
DISEASES OF THE LACRYMAL APPARATUS.

Delivered at the Royal College of Surgeons.

BY HENRY POWER, F.R.C.S.

LECTURE II.—PART I.

GENTLEMEN,—Having already in former lectures given a full description of the canaliculi and lacrymo-nasal duct, and an account of the various explanations that have been given of their action in conducting away the tears, it is unnecessary that I should enter into any details in regard to their anatomy and physiology, and I proceed at once to to the consideration of the causes that lead to Epiphora, Mucocele, and Dacryoblennorrhœa, apart from disease of the Bones, which I propose to consider in the next lecture.

Epiphora signifies an overflow of tears; and a distinction was formerly drawn between epiphora, which was held to be an overflow of tears from excessive secretion of the lacrymal gland, and stillicidium lacrymarum, which was considered to result from some obstruction to the flow of tears through the natural passages into the nose. The distinction has, however, in course of time been lost, and the signification confounded; and in most reports of cases the term "epiphora" is now applied to an overflow of tears from any cause whatever. The symptoms presented in an ordinary case are well known. The eye or eyes, for it is sometimes double, gradually fill with water, which collects and trembles at the inner canthus or lacus lacrymalis, and at length falls over the cheek or is wiped away with a characteristic action of pressure by the patient. No pain is felt, but the greater angle of the eye, including the caruncle and border of the lids and the conjunctiva, is more vascular than normal, and is tender to the touch. Close examination will sometimes show a little clear mucus or puriform mucus exuding from the orifices of the puncta, and the quantity of this may be increased by pressure on the sac. In this state it may remain for years without leading to further mischief, being regarded only as a troublesome and unpleasant affection, interfering to some extent with vision, since the tear before it overflows extends along the edge of the lower lid and produces deformed images by unequal refraction. Even in this mild form recovery is a rare event. It has a tendency to perpetuate itself. The overflow of tears inflames the lids and produces the same kind of eczematous eruption that is seen after the protracted application of water dressing; and this, again, thickens the lids and everts or inverts the puncta, whilst it tends to occlude their lumen. In more serious cases, and in cases that have lasted long, the lacrymal sac becomes distended with fluid, which sometimes can and sometimes cannot be made to empty itself by pressure, the former condition constituting blennorrhœa of the sac, the latter mucocele.

The causes of epiphora are very various, and it is of importance to recognise them: because, in the first place, an accurate knowledge of the cause may often enable us, by effecting its removal, to cure the patient; and, secondly, because, if neglected, it may easily pass into inflammation of the sac and duct, and so produce a lacrymal abscess and fistula. The causes of epiphora may be divided into three groups—those which promote increased secretion of the lacrymal gland, those which prevent the entrance of the tears into the ducts, and those which prevent their passage through the ducts, the obstruction in the latter case being either at the puncta in the course of the canaliculi, lacrymal sac, or nasal duct; each of these requires consideration.

There are certain conditions in which epiphora may almost be regarded as normal. It must have been observed, for example, by everyone on sudden exposure to cold air, since the stimulus to the branches of the fifth pair distributed to the conjunctiva causes so large an increase in the secretion by reflex action that the minute conduits are unable to take it up and convey it away, even with all the assistance that can be given of partially closing the lids to diminish the surface exposed, and of frequently winking to aid the descent of the tears into the duct. Again, when the eyes are suddenly exposed to bright light after being long kept in darkness, a similarly increased secretion is observed by reflex action through the optic nerve. And still again, the changes in the lids that are concomitant with the advance of age lead, it may almost be said naturally, to epiphora. The flabby skin of the lower lid, with its feeble circulation, easily becomes œdematous, and by its mere weight falls away from the eyeball; the puncta are no longer immersed in the layer of fluid passing over the conjunctiva, and a tear collects at the inner angle, which, together with the contracted pupil, give the aspect of dreaminess and dulness to the face characteristic of age. The eyes no longer (as Milton expresses it) "sparkling blaze." Nor did this change escape the notice of Shakspeare, when he makes the Chief Justice, in rating Falstaff, say, "Do you call yourself young that are writ down with all the characters of age? Have you not a dry hand, a moist eye?"—in addition to those other unmistakable signs of an increasing belly and a decreasing leg. An abundant overflow of tears is always produced in health by the entrance of any foreign body between the lids and its contact with their edges or with the conjunctiva. Such a discharge is, in fact, the natural mode by which such bodies are washed away. Lastly, amongst the natural conditions which lead to epiphora we may mention mental emotions, of which pain and grief occupy the foremost place.

A cause of epiphora that was long overlooked, but is now universally recognised, is error of refraction in the eye. The most common defects which in this way lead to epiphora are undoubtedly hypermetropia and astigmatism, and the explanation is sufficiently clear. The hypermetropic eye is fitted for country or out-door pursuits. The Arab or the Peruvian has little need for the exercise of his accommodation. For him long or far sight is essential to enable him to follow his occupation as a hunter, and to recognise friend or foe on the distant horizon; but when such eyes are compelled by the exigencies of civilisation to work upon near objects, some exertion of the ciliary muscle is required. The necessary work is followed by exhaustion, and the conjunctival and ciliary vessels become surcharged with blood; their tone is impaired, and increased secretion takes place not only from the main gland, but from its accessory portion and from the glands of the lids, and epiphora results.

Another cause of epiphora that is very common in practice, and constitutes the link between those which merely produce increased secretion of tears and those which prevent the escape of the tears by the canaliculi, is infarction of the Meibomian glands. This condition is very common in gouty subjects. In these the eyelids are seen to be rosy and full of blood, and on examining the mucous membrane the colour is found to be much deeper than natural, whilst here and there particular follicles of the Meibomian glands may be observed to be full and prominent; sometimes they are covered with the epithelium, but occasionally they may be found jutting out like grains of sand, and then produce intense discomfort and epiphora. In such cases they may be picked out with a needle, and resemble little fragments of coral. When there are one or two of these, many other enlarged gland follicles may be seen, the contents of which gradually and only very slowly work their way out. Not only do the asperities of these bodies induce increased secretion of tears, probably of altered quality, but by thickening and inflammation of the lid the puncta and canalicula become occluded, and the drainage of the tears is seriously interfered with.

Eversion of the eyelids is a common cause of epiphora, and acts by causing the puncta to separate from the globe, so that the puncta are no longer immersed in the fluid collected in the lacus lacrymalis. The numerous causes therefore which lead to ectropion lead also to epiphora—such, for example, as ciliary blepharitis, the cicatrisation consequent upon wounds and burns; tumours of the eye or orbit; hypertrophy of the connective tissue near the canaliculi, which has been noticed by Desmarres; swelling of the caruncles; papilloma, epithelioma, and syphilitic and rodent ulcers about the inner canthus.

Inversion of the lids is not less influential than ectropion, though it acts in a precisely opposite manner, the deviation in position of the border of the lids causing the puncta to be so closely applied to the globe that the tears, the secretion

Digitized by Google

of which is greatly increased by the irritation occasioned by the cilia, can no longer make their way into the ducts. This condition may be sometimes artificially induced by the application of bandages for many consecutive days in cases where there is slight separation of the lips of the wound after cataract operations. The whole lid in such cases becomes swollen, the compressive bandage keeps the margins turned in, and the cilia rub against and irritate the already congested and inflamed conjunctiva. MM. Galezowski and Naudier have described a peculiar kind of conjunctivitis, termed by them "lacrymal conjunctivitis," which they recognise as the consequence of the prolonged retention of the tears in the sac, and which calls to mind the opinion held by Boerhaave and many of the older writers of an increased acrimony of the humours. There can be no doubt that such conjunctival inflammation has a tendency to perpetuate itself and induce epiphora, since it is accompanied by the secretion of much mucus, which may be seen sticking about the orifices of the puncta, towards which it gravitates, and must seriously interfere with the passage of fluid into the ducts through the puncta. The same conditions may lead to partial ectropion, as well as to entropion.

Many cases of epiphora arise from injury near the inner canthus, involving the puncta, canaliculi, or sac. When such injuries have occurred, the greatest possible care should be taken in readjusting the edges of the lids with accuracy, so that the canaliculi should remain pervious. I remember seeing a child who had received an injury with the ferrule of an umbrella, which had been thrust at him in play. The surgeon who had been called in had applied a suture bringing the parts together with accuracy enough for all ordinary purposes; but lacrymation followed the accident, and on examination I found that the laceration had divided the canaliculus just on the inner side of the punctum. I reopened the partially closed wound, passed a fine probe through the punctum and distal part of the canaliculus, and with a little trouble found and passed the probe into the proximal segment. The edges of the lids were then accurately adapted, and perfect recovery resulted.

Epiphora occasionally results from congenital absence or atresia of the puncta. Swan Burnett[1] gives an instance, and states that only three cases are on record in the periodicals devoted to ophthalmology.[2] Mooren (Fünf Lustra) only noted one case in 108,416 patients. Zehender has described two cases, and Hugo Magnus two more. In Burnett's case all the puncta were impermeable. Except that of the right upper lid, which possessed a small channel, there was no watering of this eye, a sufficient proof that the upper puncta and canaliculi discharge an active function. In Zehender's case the left upper punctum was alone pervious. In Magnus's cases both lower puncta were absent, and there were no papillæ. In treating his case, Swan Burnett thought it better to search for the canaliculus than to attempt to open the punctum. He therefore made a vertical incision with scissors through the margin of the lid about two millimetres to the inner side of the papilla. He then searched, by means of a No. 2 Bowman's probe, for the canaliculus, and had no difficulty in finding it. The canaliculus was then slit up, and the epiphora promptly disappeared. Obliteration of the puncta has been occasionally observed as a consequence of the cicatrisation of a small-pox pustule. Thus Pellier de Quengsy relates a case in which he was called to see a girl at Perpignan who had suffered for some time from severe epiphora consequent on small-pox, which had been neglected on the supposition and anticipation that it would recover naturally as soon as the catamenia appeared.

Epiphora is sometimes caused by the entrance of a cilium into the punctum. I have had two cases under my care quite recently. In each the hair was one of the small colourless cilia, and it had entered root foremost, so that only the fine transparent apex protruded. Care should be taken, in removing it, that it is not broken, and it may be stated that the resistance it offers to extraction is more considerable than might be expected, perhaps owing to the ridges on the surface of the hair, and perhaps in part to contraction of the muscular tissue around the canaliculus. The displacement of one or more hairs is a frequent cause of lacrymation. I recently saw a woman aged forty who had experienced lacrymation for a twelvemonth, and in whom a mucocele had developed in the course of three weeks on the right side. On examination two hairs were found to have become inverted at the inner canthus, which irritated the conjunctiva, and caused a circumscribed redness of it. The lacrymal gland was enlarged, and presented a conspicuous swelling beneath the mucous membrane when the upper eyelid was raised. The enlargement appeared to me to be the result of reflex irritation. This led to constant hypersecretion of tears, which led again to constant distension and consequent atony of the walls of the lacrymal sac. Great improvement resulted from removal of the hairs. Monoyer[3] gives a case in which a woman, aged twenty-five, whilst throwing an ear of barley into the air, felt something sharp enter the eye. She herself removed a portion of the awn, but continued to feel discomfort. M. Monoyer, on attentive examination, saw a small point projecting from the superior punctum. On seizing it with a pair of cilium forceps, he withdrew a fragment of the awn, 6 mm. long. Only one other case of this is on record—namely, one by Kneschke, who in 1836 observed a fragment of wheat in the inferior canaliculus. It has probably occurred frequently, but has not been deemed of sufficient importance to deserve record, and it is probable that the foreign body is pressed into the canaliculus by the finger of the patient in the endeavour to remove it by rubbing, and may occasionally be the foundation of other trouble.

ABSTRACT OF THE

Inaugural Address

DELIVERED BEFORE THE

SANITARY CONGRESS,

Held at York, September 21st to 25th,

BY SIR T. SPENCER WELLS, BART., F.R.C.S.,
PRESIDENT OF THE CONGRESS.

I HESITATED for several days before complying with the flattering proposal of the Council of the Sanitary Institute to fill the honourable position of President of this year's Congress, and to address you this evening. Although a worker in collateral science and art, I could not presume to appear before a meeting of sanitary experts as an instructor, and I must beg you, while listening to me, to consider that we are all engaged in making a joint effort to draw general attention to questions of vital importance to the public health, to diffuse information, to get the people to take an intelligent interest in sanitary matters, and to bring the governing powers into a disposition to give more effectual help in carrying out such reforms as are proved to be necessary by scientific investigators. With the feeling that this is our mutual relation I may proceed; and if I trouble you with the reiteration of some truisms and the citation of facts already well known to many of you, I trust you will be patient with me, in the hope that some of the seed which may be sown broadcast to-night may fall upon fruitful soil, and, if good, may so multiply that it may be sown again and again by others, and in good time influence the multitude.

Any great sanitary improvement of the community must be the result of elaborate co-operation. We must have the combined action of the three great classes of investigators, legislators, and administrators before we can effect any good result. And if we regard sanitary reform in these three aspects, we find that a great deal of the work of investigation has been done, and that the work of legislation is lamentably deficient; while the work of administration cannot advance beyond the limits of legislation. As regards the work of investigation, we may safely assert that it has hitherto been for the most part personal, and that the waste of labour has been enormous. It is only of late that this Institute has come in aid. Three-fourths of the fifty years that Southwood Smith, Chadwick, Farr, and Trevelyan were at work, they were well-nigh single-handed. Perhaps the

Digitized by Google

foundation of such a body as the Sanitary Institute may be enough for them to be proud of; but more must follow, and it is to be hoped that before long we shall have, for the sake of life and health, an organisation as powerful as that which protects our property and our liberties. The Institute must develop into something grander and more powerful. The Colleges of Physicians and Surgeons have done and are doing much useful work; but the work is done more for the individual than the collective good. Without interfering with them—rather aiding them,—why should we not have a "College of Health"—a college which would show our appreciation of the gift of life and our reverence for the Giver?

When we speak of the prolongation of life, we think chiefly of the advantage to individuals, their better health, and their augmented power of enjoyment. This is a great deal. But it means more for the State. It may sound well to declaim against the money view of the subject as low and sordid; but it is not to be overlooked when we are apportioning merit for work done. A donation to the community of two or three millions would be looked upon as an extravagance. But what is the fact? During the forty-nine years that registration has been in force, and sanitary reforms have advanced with its annually increased information, about eight millions of people have been added to the population of the United Kingdom. We may fairly credit our reforms with a large proportion of this increase in numbers, and consequently of their money value. The result on human happiness is not a matter of calculation, but a future industrial census will show in a very definite shape the effect of sanitation in raising the economic value of the population. We cannot be far wrong if we put the average duration of human life in Great Britain half a century ago at about thirty years; now, according to the healthy life table, it is forty-nine years. The population in less than fifty years increased, as I have said, by some eight millions. Each individual of these millions was worth to the State, as is calculated, about £150. Say that only two millions out of the eight millions of increased numbers were the fruit of sanitary and medical work, their economical value was at least £300,000,000, and that a clear gain. To this we must add that the productive powers of the population depend on labour, and that labour depends upon health. Let sickness come, men are disabled, their labour ceases, and the produce of labour is lost. Formerly it was calculated that a twenty-third part of the population was constantly sick, and the products of all that labour for the time necessarily withdrawn. A great deal of this sickness has been altogether prevented, and the duration of that which comes in spite of sanitation is lessened. Happily did Richardson give form and expression to the proberb, "National health is national wealth!" and well may Froude follow with his paraphrase, "The *Commonwealth* is the *common health*, the common wellness," and add, "No nation can prosper long which attaches to its *wealth* any other meaning."

Since the formation of the Sanitary Institute, although the progress of sanitary science has not been as rapid as we desire, yet its advances have been more readily measured. The annual meetings, the presidential and sectional addresses, and the papers read in the sections, have brought important movements under notice; and as the Congress migrates yearly to new places, its information becomes more varied and trustworthy. We gather assurance of the generally improved moral and physical condition of the people. We find that infant mortality is lower; that education becomes more satisfactory as the principles upon which it should be conducted are better understood; that those who work are better paid, get wholesomer food, and dwelling-places more fit for human habitation. With all this encouragement we may look hopefully to the future and consider what are the most pressing subjects of inquiry, and which is the way of conducting our investigations that gives the greatest promise of success. The field is vast, but, as we have seen, it is not impenetrable; and obstacles are sure to yield to steady and well-directed attack. "What we want is a central power," as Lord Brabazon wrote last month in *The Times* (Aug. 30th), "which shall regulate and control local action, so that no town or locality shall be able to neglect the public health, or, in endeavouring to purify itself, shall poison its neighbour. We want a power which shall take a bird's-eye view of the whole question, and work not for the good of one locality only, but for the good of all." This is what we want, and what we must have some day. But, while we are waiting, an interim organisation of deliberative and administrative agency should be set up, as if a Ministry of Health were in power. The Local Government Board, too, with all its official completeness, like ourselves, may recomend, but cannot command. There seems to be a link missing between the knowledge of what is right and the power to apply it. This link is a Minister of Health. This Institute, united with the Parkes Museum, is bound, in my opinion, to induce all the others to make not only common cause, but joint action; or failing in this effort, it may, by increased activity, in a short time cover the ground which they now occupy. This would at once make plain the folly and waste of division. The process of amalgamation has already begun by the union of the Parkes Museum with our Institute. The National Health Society, the Ladies Sanitary Association, the Cremation Society, the Smoke Abatement Institution, and others of a like kind must follow; while such societies as that of the "Medical Men qualified in Sanitary Science" and the "Society of Medical Officers of Health" would find themselves more fitly placed and more usefully employed as sections of one united body than they now are. The active working of such a large group of philanthropic societies shows how constantly the interest in all sorts of sanitary measures has been increasing during the last twenty years, and how much it has been in the power of such feebly-supported societies to do. Our great effort at present ought to be the concentration of working power and its economical direction. With this object attained, it will not be difficult to explain the motives for special contributions, and to collect them from a public which seldom turns a deaf ear when appealed to rationally. There are many investigations which require much time, which cannot be conducted by individuals, and which are costly. The Institute, with adequate funds, could form its commissions, send outits health challengers, have its own laboratories, museums, deliberative councils, exponents, and consultants—and all this not interfering with, but rather in aid of, recognised privileges or established authorities.

In studying the various subjects to which the Institute has given attention, and the investigation of which it is still prosecuting, they may be conveniently arranged into five groups: 1, those which relate to the training and health of the population; 2, to their social comfort and well-being; 3, to the prevention of disease; 4, to the care of the sick; and, lastly, those relating to the disposal of human refuse and remains. Impossible as it is even to recall all these subjects to your minds, there are a few points upon which I cannot refrain from a word or two of comment.

1. So far as concerns the mental and physical training of children, and giving women the option of other occupations than those of domestic life, I see no great cause for alarm. It is an age in which education—at any rate for the middle classes—must be pushed far beyond the limits which our fathers thought wide enough for us. Mere rule-of-thumb work is almost out of date, and there are so many industries in which scientific knowledge and exactness are requisite, that the want of early education cuts off a young man's chances of advancement. To engage in most of the recent applications of steam power, electricity, magnetism, and chemistry—to be available in carrying out the complexities of engineering science—a workman must be something more than a mere machine. He must have head as well as hands—brain as well as muscle; and as uneducated brains are not worth more in the labour market than untrained muscle, we must be content to make some sacrifice in the culture. While we pity the few who fall in the struggle, we must remember that there is no chance for those who stand still. As for the outcry about the dangers from women taking up men's work, it is breath wasted. A great many failures will outweigh a few successes and bring the balance right. For my own part, I think women capable of a great deal more than they have been accustomed to do in times past. "To suckle fools and chronicle small beer" surely cannot be the chief end of woman. If overwork sometimes leads to disease, it is more morally wholesome to work into it than to lounge into it. And if some medical practitioners have occasionally observed cases where mental overstrain has led to disease of mind or body, I cannot deny that I also have at long intervals seen some such cases. But for every such example I feel quite sure that I have seen at least twenty where evils equally to be deplored are caused in young women by want of mental occupation, by deficient exercise, too luxurious living, and too much amusement or excitement. Again, we have heard much of late about over-pressure

Digitized by Google

from work in schools. This is one of the novelties of our time. No doubt it exists, and I think it may in part be traced to some of our sanitary success. We have reduced the mortality of early infancy. Many children who would formerly have died offhand are now saved, and find their way into the schools. They are the survivals of the least fitted. They live, but they are not strong—not so strong as the average. They have to submit to the same routine, and to be forced up, if possible, to the same standard as the rest. But the effort is too much for them. Their frames are not hardy enough to resist the mental strain. They show all sorts of nerve symptoms, disappoint the teachers, and are the types brought forward as victims of the system. The vice of the system is that it is indiscriminate. There is no revision of the recruits, and the tasks are not apportioned to the feeble powers of sanitary survivors. This is an evil which will remedy itself in time by the growing up of a larger proportion of strong children, and the present difficulty may be got over by a little patience and moderation—a little more regard to sanitary logic. The children must have training before education, and must be put upon something even less than a half-time system.

2. Of the many things which affect our comfort and well-being, some are national, some local, some residential. One of the most potent means of influencing the sanitary condition of a country is the judicious regulation of its forests. In Great Britain the Government all but ignores the subject of Forestry. There is no school for teaching the science. Every proprietor is obliged to shift for himself, or to seek foreign help. And yet by looking at the state of things in Upper India, Palestine, and Russia, we may see what mismanagement leads to. Almost everywhere, man's ignorance and recklessness has worked evil by destruction of the forests. He has deteriorated the condition of the climate, taken away the productiveness of the soil, brought on famine and pestilence.

3. In preventive medicine the great event of the year has been the publication of Pasteur's views on hydrophobia, and his treatment of it by inoculation. I must not anticipate the reports of commissions still sitting; but, in connexion with what I have previously said, it is worth bearing in mind that, astonishing as Pasteur's own personal work has been, he has all the way through been adequately seconded. He has found means and material forthcoming, suitable accommodation has been provided for his investigations, he has been buoyed up by judicious encouragement, and he has never been obstructed by legislative impediments. He has been a benefactor to his country and to the world in many ways, and his services have met with a just recognition. But we must not be too sanguine, form unreasonable expectations, and jump to irrational conclusions. As he himself wisely says, in speaking of his attempts to neutralise the poison of hydrophobia, we must wait and see the results of what has been done before we can test the value of the practice. I accept the principle upon which he acts, and believe that those who are following his lead may outrival him in the good they confer upon mankind.

4. Yet even if we were to realise the most enthusiastic visions of one of my most imaginative predecessors, and could cycle through the greater part of our century of life soundly and pleasantly, accidents must overtake some of us, and decay and infirmity must come sooner or later. This is a theme which gives play enough for intelligent thought. The rich, when sick, can afford the luxury of skilled attendance, and can hold out inducements enough for men of capacity to devote themselves to the study of medicine and surgery. But what are the poor to do? They can never alone, or without some aid or combination, afford adequate remuneration. Medical relief, as in legal phraseology it is called, is the first step to pauperism. Self-help in this matter is one of the first steps to independence. Provident dispensaries, giving members the right to attendance from medical men of their own choice at their own homes, the opening up of easy access by small money payments to the coveted advice of hospital staffs, and the foundation of clubs and cottage hospitals on sound principles, are among the best means of meeting the requirements of the sick poor. Our great establishments will always be needed for accidents and severe diseases, which there is no possibility of treating successfully in cramped and ill-supplied homes. But hospitals do not necessarily pauperise. The very poor can well accept the care in them as a gracious gift, while those who have something to spare always can, and sometimes do, make a thank-offering. On behalf of those who have had disease, who have been rescued from its immediate dangers and are in a state of convalescence, with appetite, strength, and spirits coming back slowly, and creating a craving for fresh air and a longing for the few idle days so necessary to perfect recovery, I wish to impress upon all who hear me the importance of convalescent homes. They are springing up in numbers, but more are wanted to complete the work of our City hospitals. Many patients come to them from the country and return well to the country. But what is a poor town cripple now to do when he is relieved, and hospital atmosphere bars his recovery of health? And now that the urban population is yearly augmenting in such a rapid manner, this necessity for providing for country convalescence is more and more urgent. The philanthropic sanitarian has something more to do than to fit up wards for the sick man to lie down in; he must see that in due time he may get the strength to 'take up his bed and walk.' If we cannot do miracles, we may complete our charity.

5. Even the best-regulated communities are encumbered with things which they must get rid of—human refuse, human remains. The one can be dealt with as best suits public convenience, but the other must be treated with reverence as well as security. As regards the question of the disposal of the dead, I may refer you to a lecture of mine, which has been placed in your hands, with remarks upon it by Sir Lyon Playfair, Dr. Cameron, Sir Joseph Fayrer, and Mr. Seymour Haden, with two of the last letters written by the best of the Shaftesburys. Public opinion has been veering round since the publication of the Charge of Sir James Stephen. A custom known to be not illegal will be adopted by many who have hitherto been deterred by the fear of illegality; and the Society which alone in England gives facility for it is ready to perfect its accommodation or to give place to any administrative body upon a wider basis.

When we come to speak of the question of Legislation, we, as sanitarians, find ourselves in the same plight as the rest of the world loaded with good intentions. The waste of time and energy in Parliament in party struggles has banished all possible home legislation. We must bide our time, assured that, when this crisis of angry discussion of political complications has passed, the turn will come for practical measures. We shall then settle down to a calm consideration of what is really wanted, shall have our chance of being heard, and probably get a good deal of what we ask for. Our demands will appear so reasonable, our work so useful, and our plans so feasible, that no committee will have the heart to suppress them, no Parliament the churlishness to refuse them. Only let us be prepared for the occasion, have our subjects chosen, our evidence forthcoming, our arguments marshalled, and our advocates ready. We shall have ourselves to blame if we do not make sanitary legislation the popular legislation of some sessions near at hand.

I have taken up a great deal of your time, and I must not presume much longer on your kind indulgence. But there is one matter which I must speak of before concluding, and that is the importance of our having the unsectarian assistance of all religious teachers. Sitting as we do here under the shadow of the hallowed Minster which is the crowning and significant glory of the ancient city of York, one cannot but recall to mind how for successive ages its ministers have been the benefactors of all who came within the sphere of their action. In times of ignorance, they spread light around them. In times of distress, they gave succour to the needy and shelter to the homeless. In times of sickness and pestilence, they were ever ready, at their own risk and peril, to visit either castle or cottage, with consolation for the troubled mind and remedies for the tortured body. And now, in these later days they, and others allied with them in the same holy work, come among us laymen, trained up by them in the spirit of Christian charity, to second our attempts to work the good of the people, to instruct themselves in the principles of our science, and to add the benefit of their wisdom and experience to our efforts, with as much zeal and devotion as were ever displayed by any of the bygone generations of their revered predecessors.

With such objects in view, actuated by the same spirit of good-will to mankind, and impelled forward by an equal energy, we may promise ourselves the attainment in due time of our desired end—that of contributing to the real and stable greatness of our country, by giving to it a healthy and long-lived population; for we may rest assured that, in the

Digitized by Google

words of Froude, "A sound nation is a nation that is composed of sound human beings, healthy in body, strong of limb, true in word and deed—brave, sober, temperate, chaste—to whom morals are of more importance than wealth or knowledge—where duty is first, and the rights of man are second—where, in short, men grow up and live and work, having in them what our ancestors called 'the fear of God!'"

THE ETIOLOGY OF TYPHUS FEVER,

ILLUSTRATED BY A SERIES OF RECENT OUTBREAKS IN DUNDEE AND NEIGHBOURHOOD.[1]

By ROBERT SINCLAIR, M.D.,
PHYSICIAN TO THE DUNDEE ROYAL INFIRMARY.

ON February 20th, 1884, the last two cases of the typhus outbreak of 1883-84 were removed to the Dundee Royal Infirmary, and for the next seven months Dundee was free from typhus fever.

Outbreak No. 1.—About the middle of September, 1884, a Glasgow tramp arrived in a very poor and densely populated district known as the Bog of Lochee, about two miles[2] from the centre of Dundee. The houses in the bog are one-storeyed; the population is about 200. This man was laid up for about a fortnight with a feverish attack. He was seen only once by Dr. Watt, who found him feverish, with a dusky aspect, but no rash. The case was not reported, but Dr. Watt now thinks the man had typhus. There were three other adult occupants of the house of one room and a closet, and they remained well; but on October 2nd a boy who lived two doors off in the same row was seen by Dr. Watt, who found him complaining of sickness, vomiting, and general pains. On the following day, the sixth of the illness, a typhus rash was seen. Two days later he was found to have pneumonia, and on the eleventh day he died. His brother soon after had pneumonia, but not typhus. A woman in the same row of houses had typhus within a fortnight after the boy who died. Dr. Watt heard of three other cases of febrile illness in the same district and about the same time, but they did not seem to be sufficiently severe to require medical attendance.

Outbreak No. 2.—Mrs. M——, aged thirty-two, resided with her husband and three children in a single room in Miller's Pend, one of the most densely populated parts of the West Central District, and about a mile and a half from the scene of the preceding outbreak. She sickened of a febrile disease about the middle of December, 1884, two months after the last authenticated case of the Lochee outbreak. She did not fully recover for over five weeks. The disease was not recognised as typhus, and she remained at home. Her husband took ill on Jan. 10th, 1885, was sent to the infirmary under my care on the 22nd, and went through an attack of typhus. About the same time his youngest child, ten months old, sickened of a fever and remained at home. A week after the admission of the head of this household to the infirmary the family removed to 11, Milne's East Wynd, a little further west in the same district. About the middle of February the two remaining children, and one who, though he lived with his grandmother in Littlejohn-street (Central), frequently visited his father's house, sickened, and on the 25th of the same month they were all admitted with typhus. On the same day a girl who lived in the same close was admitted with typhus. Two days previously two girls who lived in the same district a few hundred yards off, but who were in the habit of spending their evenings in the infected tenement, and doubtless caught the infection there, were admitted. On April 7th a man and a girl, and on May 21st a boy, who lived in the same close, were sent to the infirmary with well-marked attacks of typhus. T. B——, aged thirty-one, 7, Parker-street (Central), half a mile distant from this centre, sickened on April 10th, and was admitted with typhus on the 17th. There was no fever in the neighbourhood of his house, but he had been collecting rents at 11, Milne's East Wynd, where he doubtless caught the infection.

Outbreak No. 3.—The disease next appeared in Peebles-lane, Lochee, about 250 yards from the Bog, but fully three months after the last case occurred there. Mrs. F——, aged fifty-five, was seen in Peebles-lane, Lochee, by Dr. Alexander, who wrote to me: "The woman was neither fed nor clad, and all her surroundings were quite calculated to invite an attack of typhus. How she contracted the disease I am not so clear, but I am quite certain she had *typhus gravior*, and that it and nothing else disestablished her." No connexion could be traced between her illness and the cases in the Bog or in Dundee. She lived a very solitary life, in very bad sanitary conditions.

Outbreak No. 4.—On Jan. 28th, P. M'L——, aged twelve, one of five occupants of a single room in Well-road, Butterburn, on the extreme northern boundary of Dundee, and at least a mile distant from the previous outbreaks, was reported. She was removed to the infirmary next day, and went through a typical attack of typhus. She had not been visiting any house in which there had been illness. After her removal to the infirmary a female friend went to occupy her place in her mother's room. She sickened on Feb. 19th, was removed on the 25th, and had an equally typical attack.

Outbreak No. 5.—On Feb. 7th, Mrs. D——, aged thirty-four, was reported to have typhus, and next day she was removed from her house at 44, Lilybank-road (East), fully a mile distant from the previous cases. It was subsequently ascertained that in a neighbour's house in the same close, which she had frequently visited, the father and a child had been ill of supposed influenza. The mother of the head of this house also visited them frequently. She took typhus and died. On Feb. 10th Mrs. S——, the neighbour at whose house Mrs. D—— visited, and from which she caught the infection, was admitted with a well marked attack of typhus. The S—— family of three occupied an attic room, and no one of them had been visiting any house in which there was illness of any kind whatever. Indeed, these were the first febrile illnesses in the vicinity for a long time.

Outbreak No. 6.—Mary McD——, aged sixteen, 2, Lyon's-close (West Central), a mile distant from Lilybank-road, one of six occupants of two rooms, took ill on Feb. 23rd, was removed on the 27th, and went through a well-marked attack of typhus. After a very exhaustive inquiry, I failed to find the slightest connexion between this and any case of typhus or illness of any kind.

Outbreak No. 7.—Mrs. F——, aged forty-two, resided with her husband and seven children in a small low-roofed room, with a closet opening off it, in Ramsay's Pend (West Central), a few hundred yards from Lyon's-close. In March, 1885, she was in bed for three weeks. The case was not reported, but it was very probably typhus, overlooked. She had not been in contact with any fever patient so far as she knew; and, indeed, she was not likely to be, for she rarely left her own house. Subsequently sixteen persons belonging to five families residing in the same close were attacked. All of them were infected directly or indirectly by her. Although all the houses were not equally overcrowded, there can be no doubt that the smaller offenders suffered by their juxtaposition to the more serious transgressors of the laws of health. The cases were all removed between April 6th and 18th, and no fresh outbreak has occurred, although the district is one of the worst in Dundee in respect of personal cleanliness, house sanitation, and overcrowding. Nurse H——, Fever Wards, Dundee Royal Infirmary, sickened on May 16th of typhus contracted while nursing this batch of patients.

Outbreak No. 8.—R. L——, aged nineteen, resided with a married brother and his wife in an attic house of two apartments, at 3, Mitchell-street, half a mile distant from Ramsay's Pend (North-west). He sickened on March 24th, and, while feeling very ill, he removed to 6, Littlejohn-street (Central) on the 27th. On the 31st he was sent to the infirmary, and went through a well-marked attack of typhus. There was no fever of any kind in Mitchell-street, and this patient had not been, to the best of his knowledge, in contact with any fever patient; but he had certainly been insufficiently fed for some time before his illness began. C. P——, aged thirty-six, the only occupant of a single commodious room immediately above the house in which the preceding patient lived for four days, at 6, Littlejohn-street, sickened on April 14th, and was admitted on the 20th. This woman had had ample food, had been subjected to no depressing conditions, and had not to her knowledge been exposed to infection. She assured me that she had not been in any house but her own for months previously; but exactly fourteen days before her illness began the preceding patient had been removed to the infirmary. He lived in a

[1] Read before the Forfarshire Medical Association.

[2] This distance, and the distances which follow, were supplied to me by an official in the Burgh Surveyor's office.

Digitized by Google

house on the ground floor of a tenement entering directly from the close. C. P——, therefore, and every person who entered or left any house in the tenement, were obliged to pass this door; and it is very likely that this woman got infected there. No other cases were traced to this source; but in the middle of July—i.e., four months later—a man who lived in the same close as R. L——, in Mitchell-street, but on the first floor, sickened of enteric fever, was admitted on Aug. 3rd, and went through a four weeks' attack. L——'s was the first and last case of typhus, and this man M——'s was the first one of enteric fever in this neighbourhood during the year 1885. But it was speedily followed by four other cases in Polepark-road, which immediately adjoins Mitchell-street. I make no attempt to revive the obsolete doctrine of the identity of typhus and enteric fever; but I would venture to bring under notice the interesting fact of the outbreak of these two specific fevers in the same close without any ascertainable connexion with previous cases, but in the midst of conditions which cannot be described as anything like sanitarily perfect.

Outbreak No. 9.—John S——, aged eleven, resided at the New Mill of Gray, near Invergowrie, about three miles and a half from Dundee. A family of eleven persons live in an isolated, clean, dry, comfortable, and, as I can personally testify from an unexpected visit, well-ventilated house of six apartments. The boy slept with a brother in an ordinary sized, airy bedroom. The house is thirty feet distant from the steading, in which, by the way, I could see no objectionable feature. According to Dr. Stewart of Liff, who sent the boy in as a case of enteric fever, there had been no fever in the family or the neighbourhood for some time, except one case of enteric fever at Whitelawston, three quarters of a mile off. With this place, however, there had been no communication. The boy was admitted on June 20th, 1885, and was placed in one of the medical wards. On the third day after admission and the twelfth of the illness, I became satisfied that a rash, which had been present more or less since admission, was a typhus one, and he was removed to a previously cleaned and disinfected typhus ward, of which he became the sole occupant. The occurrence of this case in an isolated farmhouse; the long duration of the fever, twenty-six days, without complications; the early abdominal pain; the diarrhœa, set agoing by a dose of castor oil, and lasting four days; the tenderness in the right iliac fossa,—strongly suggested that Dr. Stewart's diagnosis was correct. But, on the other hand, the temperature during the seventeen days the fever lasted after admission was persistently of the typhus type, except, indeed, on the last day, when the morning temperature was normal and that of the evening 102·4°; the aspect, odour, and rash were as clearly typhus as they could be, and the convalescence was of the usual speedy uninterrupted character. But if there was any room to doubt the inference drawn from the clinical history, it was speedily removed by the illness of Nurse S——, one of the infirmary nurses, who attended the preceding patient during the three nights immediately succeeding his admission, while he remained in a medical ward; and eleven days later, while he was the sole occupant of a typhus ward, she looked after him for a few hours during the absence of the fever nurse. On the latter occasion she opened the door and looked to see that he was all right a few times, and once she went to his bed to put on his blankets, which he had thrown off during sleep. She had never seen a typhus patient in her life; there was no other case in the house at the time; and generation *de novo* is here quite out of the question, as all the nurses in the infirmary are well housed, well fed, and get ample time for out-door exercise, which they are obliged to take. She sickened on July 11th, exactly twenty-one days after her first exposure to the infection, and ten days after the second; the mottling was obvious on the fifth day; the rash was well out on the sixth; on the tenth day of her illness it was noted—"Rash copious for last three days over body, legs, arms, and hands; petechial on some parts." On the thirteenth day the evening temperature was 102·4°. Next day (the fourteenth) the morning temperature was 99·4°; in the evening 99 8°. On the fifteenth day it became normal, and remained so. In fact, it was a typical case of fourteen days' typhus.

The diagnosis of typhus in both these cases being unassailable, and the belief that the nurse was infected by the boy being equally so, how did he contract the disease? One thing is certain: it was not manufactured in his clean and comfortable home. Did he get it from an infected person or dwelling? When I mention that he sometimes delivered milk in Dundee for his father, it will no doubt be suggested that he may have got it in the course of his errands. But let us remember that the boy sickened on June 12th, and that all the known cases of typhus were in the infirmary fifty-three days earlier, with the single exception of J. S——, who was not removed from Milne's East Wynd until May 21st, twenty-two days earlier. But the boy's district for delivering milk was in Perth-road and Hawkhill; he never went beyond the middle of the streets going north from the latter—i.e., he was never within 570 yards of the only case of typhus known in Dundee fully three weeks before he sickened. There is another possible explanation, but it is one which may not be very readily accepted. The farmhouse is on the low ground, fully half a mile below the Dundee Royal Asylum, the sewage of which passes into a cesspool between the two houses. Of the construction of this cesspool I know nothing. But whether the whole or only part of the contents were meant to overflow, overflow it did, and carried large quantities of putrid sewage into a small stream that passes close by the farmhouse, and converted it into a foul ditch, whose thick, black, offensive contents sometimes stagnated, sometimes flowed lazily along. The boy had occasion to pass along the banks of this open sewer on his way to the asylum with milk every day, and he stated that on two or three occasions towards the end of May—i.e., between two and three weeks from the beginning of his illness—he drank from some of the less muddy parts of this uninviting stream. If there is anything in the doctrine that typhus can be generated from human filth, it might well be generated under these circumstances. Doubtless the cutaneous and pulmonary exhalations are the usual vehicles of the poison, and doubtless the human beings and their noxious excreta were not under one roof, as is usually found in typhus. Both, however, were in existence. The poisonous sewage of the hundreds of human beings in the asylum did no harm there, but it was carried outside and worked its mischief elsewhere. Two facts may be mentioned in support of my contention that the stream was poisonous, although they may not prove that it contained the specific virus of typhus fever. The fishes with which it abounded sickened and died about the same time; and the farmer's seventeen cows, which had remained perfectly well all winter and spring, were no sooner put to graze in a field adjoining the burn, from which they no doubt drank, than they all sickened, and only eleven recovered. Mr. Black, the veterinary surgeon who attended the animals, tells me they had rigors, dulness, loss of appetite, irregular rumination; pulse at first frequent and full, later on feeble and thready, in the fatal cases; temperature 102·5° to 105·3°; abdominal pain from beginning; constipation at first in all; diarrhœa in one case without, in the others only after, linseed oil; evacuations dirty, yellow, and offensive. Acutely ill from five to seven days.

(To be concluded.)

THE TREATMENT OF LUPUS BY LOCAL APPLICATIONS.

BY DR. P. G. UNNA, HAMBURG.

THE treatment of lupus by local applications is, theoretically and practically, perhaps the most important of all the more recent advances in the therapeutics of skin diseases. Even were we in a position to detect, by means of highly developed physical methods, the masses of lupus tissue in the healthy skin whilst they were still microscopically small, and then to destroy them without injuring the surrounding structures, the question would nevertheless constantly arise as to whether we could not obtain the same good results by the elective destructive action of some chemical agent on the new growth without so much wearisome and laborious surgical work. A further inducement to the study of this question would be the great desirability of a better knowledge of the chemical reactions which take place between the parasites and the various remedies which are used to cope with them—a problem which would presumably be better solved when the process takes place under our eyes, as in the case of the skin, than it could be by simply observing the results obtained by the treatment of internal organs. No one doubts, for example, that the

Digitized by Google

curing of an old obstinate patch of eczema by means of a rightly-devised chemical agent is a better process than its destruction by the thermo-cautery. Just in the same way, the treatment of lupus by medical applications is more attractive and more instructive than is a purely mechanical treatment. And the latter, with the exception perhaps of the total excision of quite small patches, is never sufficient to ward off recurrences, however thoroughly and carefully it may have been carried out. Not only, therefore, are attempts to transform the treatment of lupus into one of medical applications justifiable, but we are compelled, both in the interests of our patients and for the widening of our knowledge, to pursue this study further.

Using a strong salicylic acid plastermull[1] in order to remove the cuticle and prepare the lupoid tissue for other more destructive agents, I observed that the salicylic acid preparations alone exercised a most beneficial influence on the new growth, and that if the quantity of the acid contained in the plastermull was sufficiently large, not only was the horny layer separated from the whole patch of skin, sound and unsound, but that the tubercles themselves were destroyed and removed, the only trace of them left being some punched-out looking holes. An elective action of that sort has been well known since the days of arsenic pastes, and has clearly been explained by Binz and Schulz (*Monatshefte für prakt. Dermatologie*, Bd. i., Heft 1). I had personally obtained like results by the use of plastermulls containing arsenic and mercury, sublimate and ichthyol, and occasionally simple mercury; but in no case was the action so quick, strong, finely shaded, easily and surely regulated; nor were the little pits so clearly and sharply cut out, the healthy interstices left so entirely untouched, and the skinning over after throwing off of the affected portion so straightforward as after the employment of salicylic acid.

The next step was evidently to try the effect of salicylic acid alone on a long series of lupus cases, without assistance from any of the other remedies ordinarily used, especially arsenic, mercury, pyrogallol, and ichthyol. The one difficulty which was here encountered was the unavoidable *pain* caused by the acid; for whilst its application to thickened horny masses is almost entirely free from any painful sensations, when applied to thin epidermis, and still more to raw surfaces, the pain is really very considerable, and always lasts as long as the plaster remains on. It increases, unfortunately, in direct ratio with the quantity of the acid contained in the plaster. Thus a plastermull containing 50·0 grammes of salicylic acid is distinctly more efficacious than one containing 40·0 grammes per metre; but the pain which is produced is also proportionately greater. This, with the fact that the pain is a lasting one, constitutes a serious drawback to the use of this drug, and one which an attempt must be made to overcome if this treatment is to compete practically with other methods.

In the various cases of lupus which have come under my treatment during the last year, I have attempted to effect this in different ways, and after many failures have at length arrived at a satisfactory result. The agents which I applied successively in combination with the salicylic acid, and in each case to several patients, in order to lessen the pain, were: mercury, iodoform, cocaine, opium, extract of cannabis, chloral-hydrate, and creasote. Of these, I found opium (pure and extract of opium), extract of cannabis, and creasote alone useful. Even cocaine, on which I set the greatest hopes, proved to be entirely useless in the form of plastermulls to overcome the lasting pain produced by salicylic acid. Opium and cannabis upheld their old reputation, since the patients without exception allowed that there was a lasting diminution of pain. Still, they left much to be desired, for the plasters burnt as strongly as the simple plasters for one or even two hours before the anodyne effect developed. When it once began, the relief was certainly considerable, and lasted as long as the plaster was applied; but even with equal quantities of the acid and the anodyne painlessness could not be attained, and still greater quantities would manifestly be required to produce it.

[1] "Plastermulls" (*Pflastermulle*) consist of a very thin sheet of gutta-percha, coated on the right side with an adhesive substance (alumin. oleinic.) containing one or more medicinal substances and backed on the other side with mull (undressed muslin). "Salvemulls" (*Salbenmulle*), which are more soothing preparations, consist of ointments having a base of benzoated suet and lard, spread upon mull. They are all manufactured at my suggestion by Mr. Beiersdorf, 40, Wohlers Allée, Altona (near Hamburg).

Comparing these two narcotics on corresponding regions (e.g., the cheeks) of the same patients, I found that there was no striking advantage in either of the substances. The plasters both caused considerable pain for some time, which certainly diminished greatly, but never completely disappeared. I was therefore compelled to decide between these narcotics on external grounds, and here I found that the cannabis indica undoubtedly possessed advantages over the opium. It is, in the first place, particularly adapted to the plaster form, the cannabis plasters having a dry varnished surface of excellent adhesive power, and keeping well. The hemp extract also works up better than that of opium, and takes up large quantities of salicylic acid, which is technically rather difficult to manage.

The high price of plastermulls containing such large quantities of alkaloids (e.g., 10·0 or 20·0 grammes of extract per metre) induced me to make further experiments with cheaper materials, which could be prescribed without stint. With this object I tried creasote, mainly on account of the experience of the dentists, who have made use of it for many years for its anæsthetising properties. My expectations of it were so far exceeded that since my acquaintance with its power in this respect I have ceased to seek for any other correctant of the pain caused by the salicylic acid in cases of lupus. The first experiment with a plastermull containing 10·0 grammes of salicylic acid and 10·0 grammes of creasote (true, pure, beech-tar creasote is alone serviceable) sufficed to show me that we had in it an excellent, probably the best, anodyne for dermatological purposes. In this case, too, a period of sharp burning pain preceded a stage in which the pain was greatly diminished, but the first lasted only ten minutes, and the anæsthesia which followed was very marked, as was the case with the alkaloids. A still better result was obtained, when the creasote was doubled in amount (salicylic acid 10·0 grm., creasote 20·0 grm.). The two periods still existed, but during the first, which lasted only five or ten minutes, there was a manifest diminution of the pain, and the second period was completely painless. The same observation was made with plastermulls containing a larger quantity of salicylic acid and double the weight of creasote (e.g., 20·0 grm. of salicylic acid and 40·0 grm. of creasote). Here, too, is a short painful stage, which lasts, according to the susceptibility of the individual, between five and fifteen minutes, but during which the effect of the caustic gradually decreases, and then follows a period of painlessness, which continues uninterruptedly as long as the plaster remains on, and corresponds to the continued paralysis of the nerves of the skin by the creasote. Plastermulls containing 10·0 grammes of the acid per metre suffice for ordinary cases of lupus of the cheeks and nose; the thinner the epidermis and the better supplied with capillaries a tissue is, the less salicylic acid is required. But other conditions are presented where small lupoid nodules are deeply embedded in old sclerosed scars, produced by a long treatment with caustics and galvano-cautery, as well as in the case of that warty form of lupus (papillomatous, Aubert; verrucosus, Riehl) which occurs on the hands and feet, and which I showed some years ago to be clinically and histologically identical with the so-called anatomical tubercle (verruca necrogenica, Leichentuberkel) of anatomists and butchers—a conclusion which was doubted at that time, but which has since been proved to be correct through the discovery of the tubercle bacillus in it by several observers. Here a plastermull, containing 30 and even 50 grammes of salicylic acid per metre, is necessary on account of the abnormally increased thickness of the epidermis.

Mr. Beiersdorf (40, Wohlers Allée, Altona,) has, upon my suggestion, composed the following five plastermulls for the cure of lupus. Each roll (length 1 metre, breadth 20 centimetres, equal to ½ sq. metre) contains—

Salicylic acid.		Creasote.
10·0	grm.	20·0 grm.
20·0	„	40·0 „
30·0	„	50·0 „
40·0	„	40·0 „
50·0	„	50·0 „

Anyone wishing to avoid, from the first change of the plastermull, the painful first period after its application, and in this way to institute a completely painless treatment for lupus, may paint the raw surface with a 4 per cent. aqueous solution of cocaine ten minutes before applying the second plaster. For this short anæsthesia cocaine is as

Digitized by Google

efficient as it was found useless in attempting to produce a lasting diminution of the pain, in addition to the salicylic acid. But creasote is, to my mind, not only the morphine of the skin; it has another special value in the treatment of lupus—its antiseptic power. It is not only a correctant of the salicylic acid, but also the best adjuvant we could find. At least, excepting cod-liver oil, I know of no anti-tuberculous remedy in which I have so much confidence as in good beech tar creasote.[2] In any case of this phthisis of the skin, with which we are now concerned, it is a remedy which, applied in the concentration and in the manner indicated, deserves every consideration. This supposition has, moreover, been proved in practice to be correct. The salicylic creasote plastermull is a remedy which brings about a cure of lupus without any extraneous aid. The strongest plaster necessary for the ease should always be employed at the commencement, since at first a relatively normal skin-surface has to be attacked; under these the lupus tubercles can be seen to soften and break down. The action can be accelerated, as is the case with all plastermulls, by covering them with hot poultices. The dressing should be changed once, or at the most twice, daily, with or without the application of cocaine, and the parts cleaned, according as the susceptibility of the patient will allow it, with linimentum calcis, oil, lard, or even with soft-soap and hot water. As soon as it is found that with this simple treatment the excavations are getting shallower, and that no new ones are appearing, we may assume that the whole of the lupus nodules have fallen out. It is then advisable to have recourse to weaker salicylic-creasote plastermulls, and finally, when the lupus seems to be totally destroyed, but the process of skinning over is sluggish and a quicker completion is wished for, to still weaker means, such as mercurial-carbolic or zinc-salicylic plastermulls, or to a simple healing remedy like iodoform, ichthyol, &c. Smaller and more isolated nodules are generally completely cured under the salicylic-creasote plastermulls, even those which are richest in salicylic acid. In general, I consider it better to let the strong plastermull lie somewhat longer than is apparently necessary, so as to give a chance to even the deepest-lying nodules to shell out, and for the same reason the plaster should overlap the edge of the lupus patch by at least half an inch.

This is the simplest possible form of the treatment of lupus, but it can of course be further developed and enriched by combining it with other methods according to the individual case. These various modifications, which cannot all be mentioned here, do not alter the original idea, which consists in keeping up a continual but never excessive exfoliation of the affected portions by means of a highly elective substance (salicylic acid) which destroys the weaker tissue of the new growth, whilst a second substance (creasote) renders the process painless and at the same time exercises a directly destructive action on the bacilli.

A by no means slight advantage of this process of treatment is the cosmetic improvement which it effects, for in this concentration the salicylic acid assists powerfully in removing old stringy and lumpy scars, and after every removal of the scabs which it produces the surface is found to be in a distinctly smoother condition. On the other hand, it leaves sometimes a longer-lasting redness, which probably results from a paresis of the capillaries or from the destruction of the stratum granulosum, the layer which causes the white tint of the skin. This is best met by using an icthyolic ointment or by painting on a zinc-icthyol-gelatine preparation afterwards.

[2] I have seen the best results in cases of chronic phthisis from its persistent use for months and years in the form of keratinised pills (Dünndarmpillen) and inhalations.

BEQUESTS.—By the will of the late Mr. Little, of Fremont, West Derby, £5000 is distributed among the charitable institutions of Liverpool, the chief recipients being as follows:—Royal Infirmary, £500; Northern Hospital, £500; Royal Southern Hospital, £500; Infirmary for Children, £300; Home for Incurables, £200; Woolton Convalescent Hospital, £100; Eye and Ear Infirmary, £100; Dental Hospital, £100; Hospital for Consumption, £100; Hospital for Cancer and Skin Diseases, £100; North Dispensary, £100; and South Dispensary £100. All the legacies are to be paid free of duty. The late Mr. John Holdship, of London, has, subject to a life interest, bequeathed a sum of £10,000 to such hospitals in Middlesex and Surrey as his executors shall in their discretion select.

THE HISTOLOGY OF AINHUM.

BY C. H. EYLES, L.R.C.P. & S. EDIN.,
ASSISTANT-SURGEON, GOLD COAST COLONY.

THE affection known as "ainhum"[1] may be described as an attempt at spontaneous amputation of the toe; the little toe is the one usually affected, but in fifty of Silva Lima's cases the condition was met with five times in the fourth toe;[2] and in a specimen shown me by a friend it is a finger that is affected. The disease is usually described as one of negroes; but Crombie[3] and Crawford[4] have met with it among Hindus. It begins as a furrow at or near the digito-plantar fold of the little toe; and as this furrow gains in depth it extends laterally, its extremities ultimately meeting on the dorsal aspect. In the meanwhile the toe becomes swollen, and ovoid or globular; till, when the constricting furrow is completed, it resembles a marble attached to the foot by a short, narrow, fibrous pedicle, which may be severed by a snip of the scissors. In about one-half of the cases the furrow sooner or later becomes the seat of painful ulceration, which hastens the process. Some idea of the length of time required for the completion of the furrow may be formed from the fact that in one case, eighteen months after the extremities of the furrow had appeared on the dorsal aspect, they were still apart by a distance equivalent to about one-half the breadth of the toe. As a rule the Fanti does not apply for treatment except for the ulceration; the removal of the toe he manages for himself; hence, though the condition is common, material for examination is scarce. My remarks are based on the examination of two toes: in one, for which I am indebted to my colleague Mr. F. W. Sullivan, the furrow was complete, but the seat of ulceration and the pedicle was still bony; the other was an advanced case, the toe being attached by a narrow fibrous pedicle, and here also the sides and bottom of the furrow had ulcerated.

Method.—Both specimens were preserved whole; the first in methylated spirit for five months, and the second, after being first hardened in Müller's fluid, was transferred to methylated spirit, in which it remained for three months. For the examination of soft structures strips of tissue about one-sixth of an inch thick were cut down to bone, stained *en masse* in picro-carmine or eosine, and ribbons of sections were cut from this out of paraffin. When it was advisable to use logwood, unstained sections were cut, fixed to the slide by Threlfall's method,[5] and stained in logwood and eosine. In the whole of the first, and in the distal parts of the second, of these toes there was bone, which was first decalcified in Kleinenberg's picric acid solution, and then treated as in the case of soft structures.

The histological changes occurring in ainhum may be described as a hyperplasia so far as the epidermis is concerned; for the remainder they are mainly inflammatory. Judging from the two specimens I have been able to examine, the changes would seem to advance from the constriction to the tip; accordingly, for descriptive purposes, I shall divide the toe into three parts: *anterior*, where the changes are beginning; *middle*, where they are more or less in operation; and *posterior*, where they have been completed. These are, of course, purely artificial divisions; and while, generally speaking, certain changes occur in each, it is not unusual to find patches in the anterior part as advanced as those in the middle, and *vice versâ*.

Epidermal changes.—As a whole, the terms of the description of the epidermal changes occurring in lupus given by MM. Cornil and Ranvier[6] may be transcribed to represent what is seen in ainhum:—"Sur les coupes examinées au microscope et colorées, soit au picro-carminate, soit á la safranine, on peut s'assurer d'abord que les couches épidermiques sont plus épaisses qu'a l'état normal. Le reseau papillaire est généralement très développé, de telle sort que les papilles, saillantes, plus ou moins allongées et irrégulières,

[1] Said to be derived from a negro word meaning "to cut." Hirsch: Handbuch der Historisch-geographischen Pathologie, Bd. III., S. 504.

Digitized by Google

sont séparées les unes des autres par des prolongements ou colonnes interpapillaires du corps muqueux qui pénétrent profondement. Le derme est infiltré de petites cellules ainsi que les papilles. ..... Lorsqu'on examine le détail des coupes du lupus avec de forts grossissements, en passant successivement de la superficie á la profondeur, on voit d'abord que l'épiderme est le plus souvent épais; dans la couche cornée on constate des stries colorées en rouge par le carmine. Le stratum lucidum, la couche granuleuse sont épaissis ainsi que le corps muqueux. ..... Dans les prolongements interpapillaires du corps muqueux, il existe quelquefois des globules de cellules cornées. Les papilles irrégulières, quelquefois très allongées et pointues, le plus souvent hypertrophiées dans tous les sens, présentent beaucoup de cellules migratices et des cellules fixes tuméfiées."

All these changes are readily found in ainhum, and this hypertrophy of the epidermis may be demonstrated to the naked eye by staining a strip of tissue in logwood, when, the dermis and subdermal structures staining deeply and the epidermis either faintly or not at all, the latter is thrown into relief; and measurement shows that while at the tip of the toe it is barely one millimetre thick, it gradually increases in depth till near the constriction it may measure as much as five millimetres. And further, on viewing a mounted and stained section with the aid of a hand lens (an eye-piece, inverted, serves as well), though in the anterior and middle parts especially there is hypertrophy of the interpapillary processes, the great bulk of the thickening is found to consist of the horny layers of the epidermis.

Microscopically, one finds that the deepest cells of the *stratum corneum* in the anterior and middle parts stain deeply with logwood and picro-carmine, in the latter instance taking on the carmine stain. This staining layer is not of uniform thickness, but consists rather of aggregations of staining cells corresponding to positions of marked hypertrophy of the subjacent interpapillary processes, these aggregations being joined together by a staining band three or four cells deep. Beyond this there is nothing particular to note in connexion with this layer. The *stratum lucidum* is uniformly thickened, and in the posterior part, where the superposed stained layer ceases, it becomes indistinguishable from the layers above and beneath. In parts its continuity is broken in upon by oval or colloid masses, which are also to be found in the stratum corneum. In parts the stratum lucidum loses its character as a layer "in which the outlines of the cells, which are two or three deep, are indistinct, so that on section they appear to form a clear almost homogeneous layer";[7] the cells become distinctly marked, in which case they may be counted, and the layer may be as much as twelve or fifteen cells deep. In the anterior and middle parts the *stratum granulosum* is well marked but thickened; near the constriction it cannot be made out.

The most interesting epidermal changes, however, occur in the *stratum Malpighii*. In the anterior division the interpapillary processes are increased in all dimensions, but between adjacent processes one not unfrequently meets with slender processes, consisting of double columns of closely apposed pigmented (germinal) epithelium, which pass down, splitting the papillæ; these new processes appear to be formed by an involution of the germinal layer clothing the summit of the papillæ; at first there is a mere bud, which lengthens out; and as in process of time these double columns are separated by cells of new formation, new interpapillary processes are formed; as, however, the middle part is neared before the stage of separation is reached, these processes throw off shoots, which coalesce with similar shoots from adjacent processes, so that a network is formed, the trabeculæ of which consist of double layers of pigmented cells, while the meshes are filled with papillary material; and as these double layers are separated by newly-formed cells, an appearance is produced which may stand for a section made transversely through the papillæ—that is, there is a sheet of more or less typical prickle cells, which is perforated by round or oval islets of papillary material, each islet being surrounded by a single layer of pigmented epithelium. This appearance is best marked in the middle part, though here also distinct interpapillary processes are now and then seen, in which case there is usually a "core" formed of horny cells, which runs up into and is continuous with the stratum lucidum, and which, when taken in transverse section, presents the appearance of a "cell nest." These are not the only "nests" met with, for now and then in the sheet of prickle cells one sees a circular area consisting of cells which have lost their prickles and granular appearance, and the nuclei of which have become vacuolated. From the examination of "ribbons" of sections, I conclude that this appearance is brought about by the pressure of an advancing branched papilla, for in consecutive sections this nest is replaced by papillary material. When the posterior part of the toe is reached the entire thickness of the epidermis appears to consist of a stratum corneum; the only representative of any other layer is a layer of pigmented cells, which may take the form of diminutive processes or form a small network.

Dermal and subdermal changes. — The changes in the remaining tissues may be considered together; they consist of a hyperplasia of fibrous tissue, brought about mainly by a chronic inflammatory process. Wherever fibrous tissue normally occurs, it is found to be much increased in ainhum; further, pre-existing tissues such as bone are replaced by fibrous tissue, and scattered throughout are more or less extensive fibrinous exudations.

Vascular changes.—In the larger arteries there is one constant feature observable—viz., an increase in the thickness of the adventitia; the muscular coat is more or less normal, though in some instances there is an increase in its thickness, brought about apparently by proliferation of the connective tissue elements. It is, however, in the intima that the most marked alteration is observed; while in some vessels there is no such change, in by far the larger number the lumen is encroached upon, even to obliteration of the smaller vessels, by the much-thickened intima; there is, in short, endarteritis obliterans. As the vessels become smaller and capillary, they are surrounded by either fibrous tissue, full grown or developing, or by a copious small-celled infiltration—circumstances which to a large extent determine the characters of the different parts of the section; thus the dermis and papillæ in the anterior part of the toe are chiefly cellular, but proceeding backwards they become more and more fibrous, till near the constriction they appear to be made up of dense fibrous tissue. These conditions also modify the appearances seen; thus in the more fibrous parts a small vessel in longitudinal section would be represented by adjacent strands of fibrous tissue lined by a single layer of swollen endothelial plates, while in the cellular portions one may meet with a nodule, in the centre of which is a minute vessel, perhaps obliterated, surrounded by a delicate fibrous reticulum having a circular disposition, in the meshes of which there is an abundance of small-celled infiltration, an appearance not wanting in suggestions of incipient tubercle. In the middle part of the toe, especially, the capillary loops of the papillæ appear to undergo a hyaline change; the endothelial plates become fused together, so that the vessel appears as a tube formed of continuous translucent material; and in transverse section the capillary appears as a ring of stained material, on the inner aspect of which a swollen endothelial nucleus may project. In the veins the chief alteration is the increase in the thickness of the adventitia, together with which the endothelium is swollen.

Glandular changes.—The alterations in the sweat glands are by no means constant; in some instances the only perceptible change is in the increase in the thickness of the membrana propria by the addition of white fibrous tissue; in others the alterations are more decided. In the distal division of some of the coils there is distinct evidence of proliferation of the glandular epithelium—that is, the single layer of cells has given place to epithelium three or four cells deep. These cells may be distinct, the more internal ones undergoing fatty degeneration, in which case the lumen is filled with detritus; or the cells may be fused together, forming a granular protoplasmic mass, in which are scattered nuclei three or four deep; and, further, this mass may be broken up into irregularly triangular fragments. On viewing transverse sections of the proximal division of the coil in picro-carmine or eosine sections with a low power, one finds that some of them are divisible by their staining properties into two parts—an internal part immediately surrounding the lumen, which stains deeply, and is sharply cut off from the external part, which stains more lightly; and even with a high power the homogeneous, glistening, translucent appearance of the internal part gives the impression that it is an enormous development of the internal limiting membrane. When, however, thin sections are stained in logwood, this internal part takes on a bluish

[7] Quain's Anatomy, 9th edition, vol. ii., p. 237,

Digitized by Google

tint, and, focussing carefully, one sees in it at tolerably regular intervals a single layer of four or five nuclei; and on examining a number of sections, indications of division of this circular band into areas, each containing a nucleus, are met with; in short, this band consists of the internal layer of cells which have become fused together and transformed into a homogeneous glistening material, which is certainly not waxy, for it does not give any specific reaction with methylaniline violet; it is probably hyaline or fibrinous in nature. In such cases, where only the internal part is so converted, the outer layer of cells presents nothing beyond a certain amount of proliferation; frequently the entire thickness of the proximal division is so affected; but in all cases the internal limiting membrane is involved, and the transformation appears to be accompanied by a swelling of the tissues concerned, for the lumen is much encroached upon, being often a mere slit, and sometimes is so much reduced that only on careful focussing it shines through as a fine "leech-bite" opening. This hyaline or fibrinous transformation is met with not only in the major part of the proximal division and duct, but extends also into the distal part, in which case the material is broken up into fragments having rounded contours.

Osseous changes.—In one of the specimens I have been able to examine, the joints and bones were sufficiently preserved to enable one to judge of the seat of amputation, and in this instance I find that the plane of constriction passed through the middle of the first phalanx. In the other instance the joints were effaced, and the only part in which the knife came down upon bone was in the distal part of the toe. The histological changes occurring in the bone are those described as *rarefying ostitis*. On the whole, the process advances with tolerable regularity from the periosteal side; but towards the centre the destruction of bone occurs not only irregularly but very rapidly, so that the greater part of the interior is excavated; and as there is but little attempt at new bone formation, the cavities formed are filled with a reticulum of delicate fibrous tissue supporting capillary vessels and a few oil-globules; new capillaries appear to be formed in this medulla, which becomes infiltrated with a small-celled exudation, giving way ultimately to fibrous tissue. What one sees on transverse section, then, is a rim of bone surrounding a cavity filled with "medulla," such as that just described, into which long, irregular, jagged processes of bone are projected from the rim. This method of replacing bone by fibrous tissue does not seem to be the only one at work, for sometimes, situated in the midst of fibrous tissue, small fragments of bone with one or two perfect Haversian systems may be seen, in which case the animal basis of the bone is found to run into and be continuous with the surrounding strands of fibrous tissue.

Regarding the lymphatics and nerves, I have taken no special steps to study the changes occuring in them, and my observations are too few and imperfect to admit of being put into any shape.

Causation.—"We have not been able to obtain any clue to the primary cause of the disease," says Crombie,[8] "but it seems to be essentially manifested in hypertrophy of the skin of the little toe near the digito-plantar fold, and of the tissues surrounding its middle and distal phalanges, with an attempt at spontaneous amputation at or near the first inter-phalangeal articulation, and in most advanced cases in conversion of the bony structures of the phalanges into fibrous tissue."

The process we have seen is essentially chronic, months, even perhaps years, elapsing before the furrow is sufficiently advanced to result in amputation; and at the end of this time the changes are such that with certain modifications the terms of the description would apply equally to lupus, in which there is dermal and subdermal inflammation, with epidermal hypertrophy, and which is placed by Ziegler[9] among the "inflammations of the skin." Of these conditions—viz., inflammation and hypertrophy—which occurs first in point of time in ainhum? and in what relationship do they stand to one another? Clinically the epidermal hypertrophy and furrow formation are first observed; and I believe that these bear a causal relation to the other changes; that is, the inflammatory and trophic phenomena are due to changes which follow pressure, mainly perhaps on the vaso-motor nerves; so that the question is resolved into one of the method of production of the furrow. In epidermal hypertrophies expressing themselves chiefly in hyperplasia of the horny layer, there is an *outgrowth* constituting the various callosities met with. When, however, the hyperplasia is more rapid there will be increase in the dimensions of the interpapillary processes. If the hyperplasia be yet more rapid, or be due to some direct stimulus, not only will these occur, but there will be a tendency to invade the corium by *ingrowths* of epithelium, and there will be "clusters or rolls and strings of epithelial cells altogether diverse from any normal mode of grouping; and the same may be observed in skin wounds which are in process of repair by epidermic growth and multiplication."[10] These epidermal changes we find occur in ainhum; but they also occur in epithelioma, and in Fig. 62 of Ziegler's Pathological Anatomy we find that while the proliferation of epithelium brings about a general increase in height, *in situations where there is a direct "ingrowth from the epidermis" there is a corresponding depression of the surface.* In a section of epithelioma in my possession this depression amounts to a furrow readily visible to the naked eye, and the microscopic appearance is very instructive. Neither in the sides of the furrow nor in its immediate vicinity is there any epithelial hyperplasia, but at its deepest part the rete Malpighii suddenly enlarges, throwing out long finger-like processes, which invade the corium.

It is in this manner that I seek to account for the furrow formation; as to the epidermal hypertrophy on which it depends, I believe the cause is to be found in external and accidental circumstances. From its position the little toe is particularly liable to injury; further, the digito-plantar fold of this toe is deep, and favours the retention of foreign bodies, as sand, grit, &c.; and the presence of a crack, fissure, or wound in the fold, assisted by the irritation of foreign bodies, if continued for any length of time, would supply the necessary factors for hyperplasia; and the fold itself not only is favourable to furrow formation, but decides the direction of the furrow. In the first instance there would be simple hypertrophy, then active hyperplasia, by which the papillæ would be pushed down and strangled; the epithelial cells, being thus "removed" from the blood-supply, undergo horny change. In the meanwhile pressure on the subjacent nervi vasorum sets up vascular changes, which bring about epithelial changes in more distal areas, and thus the process advances anteriorly—i.e., in the direction of the arteries.

New Hampton.

[8] Quoted by Crawford, loc. cit. So also Hirsch (loc. cit.) says, "Ueber die Ursache des Ainhum herrscht ein vollständiges Dunkel," and quotes from Silva Lima to the effect that "les causes qui le déterminent sont absolument inconnues."

SOME SUICIDAL OR OTHER CEPHALIC INJURIES I HAVE SEEN.

BY BRIGADE-SURGEON W. CURRAN,
ARMY MEDICAL DEPARTMENT, RETIRED.

WITHOUT pretending to say that I have personally seen all the cases recorded below, yet I have been brought one way or another into such close contact with the individuals they include as justifies a reference on my part to them, and whatever concerns the vitality of the brain or of its coverings deserves consideration at the hands of the surgeon. No organ of the body is at times more susceptible of or indifferent to the effects of accident or injury, and a blow or a fall that would prove innocuous in one instance, or under certain circumstances, is instantaneously fatal or permanently injurious in another. Thus one falls, from a blow or otherwise, on an iron rail or on the kerb-stone, and never speaks again. A second falls from a side-car or a donkey-cart, and "receives such injuries as"—to use the euphemism of the press—"terminated fatally in a few minutes." A fourth rolls over the fire-irons or the door-mat, and is taken up in a dying state; and I have just heard of an instance in which a snowball was said to have produced the fatal effect. Reticence or reserve is, therefore, more becoming on the part of the medical man, in presence of this kind of injury, than dogmatism or self-assertion, and the instances that occur at police-courts and elsewhere in which a fracture of the skull is overlooked at the time, while paralysis is sometimes mistaken for drunken-

Digitized by Google

ness, "ought to inspire reserve as to our diagnosis, and caution as to all our other dealings with this delicate, but withal long-suffering organ."

The subject deserves attention also on other grounds. It is surrounded with the popular prejudices or prepossessions of ages. By some any grave injury to the head that does not prove immediately fatal is regarded with incredulity or amazement. It is held up as a "miraculous escape" to the admiration or wonder of the public; travellers gloat over it, while "specials" exaggerate it, *more suo;* and, finally, escape from it is sometimes ascribed to a particular interposition of Divine Providence. At times, also, it proves a blessing rather than a curse to the subject of it, and the latter has been occasionally relieved by it from a life-long infirmity or otherwise incurable disease. So the wonder grows by what it feeds on—*l'appétit croit en mangeant*, and the popular fallacy or illusion is turned into an article of faith. But these views are propounded in one form or another in all our leading text-books, so that I need not dwell upon them in a medical periodical, and for the rest I have dealt with this phase of the question at greater length elsewhere.[1]

In discussing this subject, I will first give brief abstracts of the cases in point that came under my own cognisance, and I will then deal with them in such fashion as their individual features may suggest or their more striking peculiarities may require. I will then add such post-mortem results as transpired through them either in my own hands or in those of other competent witnesses, and the military surgeon has opportunities of this kind by virtue of his office which are generally denied to the civil practitioner. It is in this sense that the series is now submitted for publication, and it is in this sense only that they can claim a hearing from my brethren.

CASE 1.—A young officer was returning to his bungalow late one night after dinner in a station in the north-west, when, the weather being at the time close and sultry, he bethought himself of the propriety of bathing. Happening to pass at the time by the station bath, it occurred to him that a dip in its cooling waters might cool his fevered brow. He was, I believe, just then "feverish," and whether he was otherwise flushed or excited I am now unable to say. He undressed accordingly and mounted the platform from which "headers" were usually taken, but unfortunately the water had been let out some hours previously for renewal, while the time for its reflow or readmission had not yet arrived, and meanwhile he had either forgotten or entirely overlooked this arrangement. Plunging therefore confidently, from a height of, say, twelve feet or more, into the now empty basin, his head was dashed with all the force and all the momentum of such a fall and such a weight against its concrete bottom, and was reduced to an indistinguishable pulp on the spot. A gentleman, who saw the remains a few hours afterwards, assured me that the features were hardly recognisable, so great was the discolouration of the parts. Another said that the body was so doubled up in the bath as to resemble a sleeping hedgehog or a mass of meat in a butcher's shop, and the bones of the cranium and face were literally smashed to pieces.

CASE 2.—J. S——, aged twenty-one, was brought to the hospital in a helpless state, caused by jumping head foremost from a height into a pond of water that was only two feet deep. He was perfectly sensible, but complained of pain in the top of his head, and there was great tenderness on pressure or after movement of any kind over the sixth cervical vertebra. No displacement could, however, be discovered in this quarter, but there was loss of motion and sensation over the greater part of the trunk. The penis was erect and the pulse slow and full. He slept well during the night, but became suddenly unconscious soon after vomiting on the following morning, and other symptoms of nerve paralysis or irritation supervened shortly afterwards. The breathing became stertorous, the pupils were contracted, and the conjunctivæ were somewhat injected. The temperature ran up to 109° the previous night, while the sphincters became relaxed at the same time, and, growing weaker, he died about 10 A.M. the same day, or within sixteen hours of the time the accident occurred. After removing the brain the blood flowed freely for several minutes from openings in the superior petrosal sinus, and blood was also found extravasated into the sheaths and interstices of the cranial muscles. The atlas was fractured perpendicularly on its left side near its process. The cord itself exhibited some softening over a patch that corresponded with this, and a further search brought to light a further transverse fracture through the body of the fifth cervical vertebra.[2]

CASE 3.—F. R——, aged thirty, a robust and muscular man, was brought to the hospital about 8 P.M. in a state verging on insensibility, the result of a fall on his head and neck, which he had just sustained in the regimental gymnasium. He was trying to "circle" the longitudinal bar of a portion of the apparatus, when, his hands being moist through perspiration &c., he fell as above, and had to be carried to the hospital. He was sensible enough to give a collective account of the accident an hour and a half afterwards, and he could also move his arms at this time. But there was an absence of sensation in the left forearm, and the trunk was quite paralysed. On turning him over on his left side, the back of his neck was found to be very tender and somewhat swollen, but he made no complaint of any other illness or uneasiness, and he felt easy when lying quietly in the recumbent position. The respiration was, however, in part diaphragmatic and 40 per minute, while the pulse was 80, and he was somewhat relieved by a purgative enema.

A diagnosis of concussion of the spine was arrived at, and the priapism that supervened during the night enhanced this impression. The lethargy that subsequently appeared added considerably to the gravity of our prognosis. He, however, progressed fairly during the forenoon, and remained *in statu quo* till about 4 P.M., when his condition changed materially for the worse. The breathing became hurried and gasping, the upper part of the body was convulsed, and he lost his speech and consciousness. He was, in short, dying, and he expired quietly about 5 P.M. On section, fourteen hours afterwards, it was found that a dislocation had occurred between the fifth and sixth cervical vertebræ looked at from behind. The upper vertebra was displaced to the left and thrown slightly forward; but there was no fracture of either, or, indeed, of any kind, and the ligaments appeared to be stretched rather than torn. There was no laceration of the cord or serous effusion into its sheath, and if we except a few red spots here and there on its surface, there was no evidence of any acute or active inflammation anywhere.

As soldiers, to whom these remarks particularly apply, generally commit suicide by shooting themselves through the head, we may easily surmise the condition of that structure after it has been penetrated by a bullet that is fired point blank from a Martini-Henry rifle "at an initial velocity of 1443 feet per second of time." As a matter of fact the destruction of its component parts is very considerable, but yet not quite so bad as one might expect under the circumstances. The old Brown Bess bullet did much greater injury, and often left behind what is called "a shocking sight." Not so, however, with our present weapons; for such is their lightning speed and terrific force with which the missile is propelled by them that it crashes through the tissues without leaving so much as "a wrack" behind, and the aperture that is left by it in the chest[3] or abdomen has little that is striking or even suggestive about it. The attitude of the victim, which is generally standing or reclining backwards either on a cot or against some door or wall, may have something to do with this. So also may the seat of entrance, which is generally through

[1] THE LANCET for December 17th and 24th, 1881. I may be here permitted to adopt as my motto for this paper, the saying of Dr. West, to the effect that "I have always regarded mere compilation, uncontrolled by large experience, as more apt to perpetuate error than to diffuse truth."

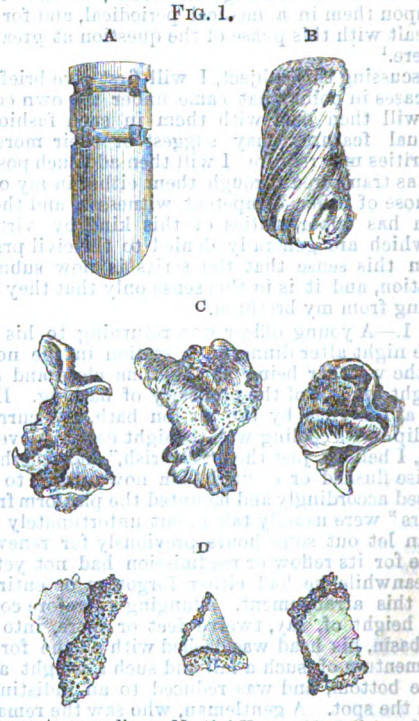
[2] I learn from a friend who witnessed the occurrence on the spot that an acquaintance of his fell on a similar occasion to that mentioned within, at Naples, head foremost on a broken bottle, the edges of which penetrated the skull, and could not be extracted during life. He died shortly after being taken out of the water.

[3] In a case of self-inflicted chest-wound of this kind I saw many years ago at Shahjehanpore, we had to stretch the skin of the part ere we could make out the aperture of entrance of the bullet. Similarly in the case of a native who was shot through the perineum by the side of the sphincter ani as he presented that part in mockery to the foe during the Huzara campaign, we had to put the neighbouring structures on the stretch to enable us to find out the opening through which the bullet or slug had entered his body. And as regards that life-long misery which is alluded to elsewhere, and which was so common in the days of Brown Bess, the Duke of Buckingham tells a story in his "Memoirs of the Court of George the Fourth," vol. ii, p. 223, of the Hon. Col. James Hamilton Stanhope, which is so pertinent to our argument that I do not hesitate to reproduce it here. It runs to the effect that "under the influence of nervous depression, resulting from an unhealed gunshot wound received at the siege of St. Sebastian, he went into a retired part of the estate and suspended himself from the bough of a tree"; and many cases occurred under similar irritation or instigation in those days.

Digitized by Google

the mouth or under the jaw, these two parts being selected in consequence, as I assume, of their affording a rest or resistance against the foot, or rather its big toe, from below. However that may be, life must be extinguished instantaneously under either contingency, and that seems to be the only redeeming feature of this horrible procedure.

CASE 4.—C. McD——, aged twenty-six, a man of fairly temperate habits, who has had only one attack of ague within the last six months, and who was so well the night before his death that he played at backgammon with a comrade, asked this same comrade for some ammunition the following morning. This request excited no suspicions in his friend's mind, as they were both engaged at the time in rifle-drill, and having secured this he soon afterwards retired into an empty room, and there shot himself through the mouth. He was thrown back by the force of the explosion on an empty bed, and on examination three hours afterwards, the whole of the upper portion of his face, as well as the front of the head, were completely blown away. The upper lip was split in two, and the nose, the eyes, the forehead, and a large portion of the brain were carried away by the bullet.



CASE 5.—A. S——, aged twenty-one, a person of strictly sober habits, was in his usual health and spirits on the night preceding his death. Having been "warned" as he was going to bed by a non-commissioned officer for second-class drill the next day, he expressed some surprise at this intimation, and got up in a sulky mood the following morning. He had been previously reprimanded or punished for dirtiness or inattention on parade, and he resented this, *more suo*, by "sulking" at meals and keeping aloof from his comrades. As they were sitting down after the morning exercises of their corps to breakfast in one verandah of their barrack-room, they heard a shot in the opposite one, and on running towards this, they found A. S—— dead in it, with his rifle lying between his feet. He had, in short, just shot himself, and on examining the body four hours afterwards, the whole of the upper portion of the head above the eyes was blown away. The brain, or such part of it as was enclosed in this cavity, went with it, and the scalp, being severed in a straight line, presented just such an appearance as is produced by a skilled dissection for a pathological purpose. So eager was he, withal, to shuffle off the mortal coil that he did not take the trouble of removing his right shoe. He enclosed it instead in the loop with which he drew the trigger, and with which he thus summarily ended all his earthly troubles.

CASE 6.—P. Q——, aged twenty-three, came to the hospital with an earache about 8.30 A.M. on May 7th, and had his ear syringed for what was considered a suppuration of the external meatus. He had previously suffered from pain in this same ear, and he intimated on this occasion that the former pain had returned to it with such severity that he had several times waked up during the night in agony. Some ordinary treatment was enforced, but he was not even detained for the day, and he did not apparently derive much benefit from his visit. On returning to his quarters he walked deliberately into one of the verandahs of his barracks with a loaded carbine, which he had surreptitiously removed from one of the racks, and literally blew his own brains out; that is, the cerebral mass was expelled through a hole in his cranium, and projected to a distance of several yards from where he lay. On inspection, four hours after death, the face was found to be fearfully disfigured, being quite cleft asunder, while its bones were broken up into small fragments. The roof of the skull was burst open, and its contents were extruded. The lower jaw was also broken in three places. Brain tissue protruded through both the eye-sockets, and so great, in a word, was the destruction of these parts that the ear lesion could not be traced. The aperture of entrance of the bullet was surrounded by a dark ring, the result of the adhesion of the ignited powder, and the sight was altogether a sickening one.

CASE 7.—J. K——, aged thirty-four, had been in a desponding state of mind for the two or three days that preceded his death—through, it was said, jealousy. Going early on the morning of the 16th of June into the sergeants' mess of his corps, he placed his firelock under his chin and discharged the contents of it into his head. The result was that the left side of his head and face was literally smashed to pieces, the temporal as well as the parietal bones being fractured and forced outward; and there was a perpendicular fracture of the frontal bone, which extended from its outward orbital plate to its upper border. The left lobe of the cerebellum was a mere pulp, whilst the middle lobe of the right hemisphere was lacerated and some of the fragments figured below were found in this cavity. (See Fig. 1.)

My view of these fragments is this. The bullet whose force we may well suppose was somewhat diminished by its impact with the lower jaw, which, it must be remembered, it had broken into several pieces, then struck the lower edge of the superior maxilla, and was by this broken up as shown below. The larger portion flew away, while the others, penetrating with their necessary bone-fragments the head, through the palate, left behind them such an opening into the interior of the skull as admitted the slightly forcible insertion of my right hand. The torn appearance of the facial muscles and the direction of this rent confirm this view; so do the weight and shape of the fragments shown in the figure. They scarcely amount to half the size and weight of an ordinary artillery rifle-bullet, and they were

FIG. 1.

A represents an ordinary Martini-Henry rifle-bullet; B, a bullet that has passed through the head as well as through the ceiling, and then fallen on the floor. C represents the larger fragments of one bullet; while D represents a finer subdivision of the elements of another; and both were found mixed with the brain tissues of two different suicides.

found as above scattered over the sulcus that separates the hemispheres.

CASE 8.—In this instance a cavalry trooper shot himself through the mouth, and the result shows that no hard-and-fast line can be drawn as to the behaviour of lead in presence of bone. A good deal will doubtless depend on the velocity and composition of the missile itself, as well as on the quality of the powder by which it is propelled, and no two craniæ are, as all pathologists know, precisely alike. Then, again, the resistance it meets or the distance at which it is discharged, however small that may be, modifies its course, and so we find very different appearances in subjects of this class. In one we find a whole side of the face shattered to pieces, while the room in which the deed is done is strewed with fragments of bone, brain, and flesh; in others there is no very appreciable displacement or deformity of any kind, and yet the result is necessarily the same in all. In this instance the bullet entered the skull through the mouth, and escaped from it at the junction of the two parietal and occipital bones. It took away with it about two inches of each of these, and also severed in its passage the superior maxillary bones. The explosion of the powder completely destroyed the soft parts within the mouth. Finally, passing almost unchanged as in Fig. 1 (B) through the ceiling overhead, it dropt spent on the floor below,

Digitized by Google

and produced very little impression on either of these structures.

CASE 9.—A young man who had shot himself through the head in a railway carriage was handed over to the police on his arrival at Warrington, on his own confession, that he had attempted his life. Declining the use of a cab, he walked to the local infirmary, a distance of a quarter of a mile, and was quite conscious and collected on his arrival at that institution. On being examined, a small circular wound was found about an inch and a half above the right external angular process of the frontal bone, just behind the temporal ridge. With the exception of some nausea and vomiting, there was no evidence of brain lesion present, but a small punctured fracture could be discovered in the skull, and on exposing this, the brain could be seen to be wounded, "the track of the bullet extending to an unknown depth." He survived till the 30th of the month—i.e., nearly six days,—having had a good deal of twitching and vomiting in the meanwhile, and his last night was distinguished with almost continuous convulsions. He had been more or less conscious towards the end.

On section a fragment of the inner table was found lying flat between the dura mater and the arachnoid. The surface of the latter, where it covered the right hemisphere, was inflamed and covered with pus, and on slicing the former the bullet was found to have entered the brain in the line of the fracture, and to have taken a direction downwards, inwards, and slightly backwards through the genu of the corpus callosum to lodge in the anterior part of the corpus striatum. A somewhat truncated "remainder" (I can scarcely call it a fragment) of the bullet was found at this spot, and it, as well as its sounder fellow of the same batch are well represented in Fig. 2.

FIG. 2.

Revolver bullet and its truncated remnant.

Commenting on this case in the *British Medical Journal* of April 16th, 1881, Mr. Richmond, under whose (subordinate) care it occurred, truly observes that its history is somewhat phenomenal. The patient not only walked firmly from the railway station to the hospital, but he retained consciousness for sixty hours afterwards, and, comparatively speaking, fair health up to within the last twenty-four hours of his life. Even then the gravest symptoms appeared to be attributable to the changes that were produced on the surface rather than to those that took place in the interior of the brain. Readers of works on military surgery must be so well acquainted with instances in which bullets or other articles become encysted within the brain for considerable periods that I need not enter into any details respecting them here.

(To be concluded.)

SUCCESSFUL CATARACT EXTRACTION FROM AN INSANE LEPER.

BY BEAVEN RAKE, M.D.LOND.,
MEDICAL SUPERINTENDENT OF THE TRINIDAD LEPER ASYLUM.

IN THE LANCET of Feb. 20th, 1886, Mr. Bickerton relates a case of successful cataract extraction from a lunatic. I have therefore thought that a short note of a similar operation, performed on a patient who was suffering simultaneously from leprosy and insanity, might perhaps be of interest.

G——, aged thirty, a Hindu immigrant, was admitted to the Trinidad Leper Asylum on Sept. 10th, 1883, with a history of anæsthetic leprosy of thirteen years' duration. There was characteristic deformity of the hands. On Jan. 8th, 1885, it was noticed that he talked incessantly, and was often very noisy, causing much annoyance to the other patients. He had been more or less demented since his admission, but had become much worse lately. He was not dangerous to himself or others. On Feb. 20th the left wrist was found to be much swollen. There was effusion of fluid, and the hand was flexed towards the radial side. Grating was felt in the joint, and the carpus could be dislocated forward on to the anterior surface of the radius, reminding one of a case of Charcot's disease. There was no pain on manipulation. The carpal bones appeared thickened, and the fingers were shrivelled and contracted. There was no history of injury, and no other joints were similarly affected. He said this condition of the wrist had come on soon after the onset of the leprosy.

On May 7th he was found to have double cataract. He could see a very little with the right eye, but not at all with the left. He appeared to have lost the sight of the left eye for a long time, but only recently to have noticed the impairment of sight in the right eye. As the conjunctiva appeared to be totally anæsthetic, the left cataract was extracted without chloroform by the modified linear operation. He made no complaint of pain. On opening the capsule a little soft whitish material escaped, but the greater part of the cataract was yellowish and very hard. The extraction was completed with the help of the scoop. As soon as the pupil was cleared he was able to see a little. The eye was treated in the usual way with atropine solution and cold water dressings. Fragments of the cataract were stained with magenta, but no leprous bacilli could be found. Soon after the operation he took off the bandage himself, but it was at once replaced, and he did not take it off again.—9th: Pupil clear. Not much injection. Sees a little. Atropine repeated and bandage replaced.—12th: Pupil clear. Wound has gaped a little, and there is slight prolapse of iris. Atropine repeated.—14th: Conjunctiva very injected. Prolapse almost the same. No complaint of pain.—19th: Iris has settled down flat. Conjunctiva still injected. Sees hand when held up, and touches it when told to do so.—23rd: Injection gone. Iris settled.—June 2nd: Firm cicatrix. No prolapse. Pupil clear. He walks with a jerky movement, lifting his feet high from the ground.—9th: The right cataract was extracted in a similar way, but was found to be softer than the left, and there was some difficulty in getting it to present well. Escape of vitreous was noticed after the operation. Atropine was used, and both eyes at once bandaged.—16th: Suppuration going on. Protruding vitreous opaque. Pain and œdema of lids. Left eye unaffected.—23rd: Right eye settling down. Pain and inflammation gone, but eye contracted and blind. The left eye was quite unaffected, so the bandage was discontinued.—March 15th, 1886: Counts fingers with left eye at 10 ft. Cicatrix firm. Small pterygium growing on each side of cornea. He is still demented, but quieter than he was, and will generally answer questions rationally.

This case seems interesting as illustrating the fact that cataract extraction may be successful under such adverse conditions as the restlessness of a lunatic and the presumably impaired nutrition of a leper, though this latter point I am prepared to doubt. I am collecting statistics, which I hope to publish at some future date, to show that operations on lepers are more successful than is commonly supposed. The complete local anæsthesia due to the leprosy served well in place of a local anæsthetic. I had hoped for success in both cataracts, but perhaps I was in rather too great a hurry to extract the second. Had I waited a few months longer till it became more mature, there would probably have been less difficulty in extraction, and the escape of vitreous might have been prevented. Fortunately there was no sign of sympathetic ophthalmia. Though bearing but remotely on the subject, I may, perhaps, be allowed to refer very briefly to the interesting concurrence of the effusion in the wrist with the jerky gait. Have we here a case of tabes with Charcot's disease independent of the leprosy? or are these leprous changes in the cord and nerves causing arthritis? or is the affection merely an exaggerated form of the joint disease, so common in leprosy, and the jerky gait due simply to anæsthesia? Some day perhaps, a necropsy may give me an opportunity of attempting to answer these questions, or at any rate of referring the specimens to a London Society.

AT some villages in Croatia, chiefly inhabited by immigrants from Herzegovina, cholera has been present for some time, but its existence has been kept secret by the inhabitants. Physicians have been assaulted both in Croatia and Istria, the populace mistaking them for poisoners.

ST. THOMAS'S HOSPITAL.

A CASE OF SUPRA-PUBIC LITHOTOMY IN A BOY; RECOVERY; REMARKS.

(Under the care of Sir WILLIAM MAC CORMAC.)

THE following is important as a contribution to the list of cases of supra-pubic cystotomy in boys where the wound has healed by first intention. Within a week after the operation the wound was firmly healed and the patient practically well, there being thus considerable saving in time as regards the healing of the wound compared with that occupied in perineal cystotomy, and much less discomfort during the process of healing. With regard to the emasculation of the patient which occasionally follows perineal cystotomy, Dr. Haemstadt, quoted by Dr. Tremaine, in a letter on the subject,[1] says, "Only one of eighteen whom I cut as boys, grown to manhood and married, has had issue, so far as I could learn," thus giving confirmation to the view expressed in the remarks. During the last session of the Clinical Society[2] the question of lithotrity in boys was introduced, and its more general employment advocated. This operation has met with much favour in some parts of India, and its performance has been followed by excellent results. Both methods of operating are under consideration, and additional facts will doubtless be brought forward during the next few months.

R. R——, a male, aged seven years and a half, was admitted on July 20th, 1886. The patient was said to have complained of pain in passing urine for the last eight months, the pain being referred to the end of the penis. He has had frequent micturition, but at no time has blood been noticed in his urine, nor sudden stoppage of the stream observed.

On July 23rd, under chloroform, the bladder was sounded by Sir William Mac Cormac, when a small, hard stone was detected. On the 31st, Mr. Tyrrell having placed the patient under chloroform, Sir Wiliam drew off the urine through a No. 2 catheter, afterwards washing out the bladder carefully with a 5 per cent. boracic acid solution. He then with the solution distended the bladder until the dulness reached about half-way to the umbilicus. The catheter was then plugged and allowed to remain. To raise the bladder still further out of the pelvis, a small Barnes's bag was placed in the rectum and distended. This lifted the bladder to within one inch from the umbilicus. An incision two and a quarter inches in length was made in the middle line, terminating just above the pubes. The linea alba was divided and the recti retracted outwards; the anterior surface of the bladder then came to view. No peritoneum was seen. Two stout silk sutures were passed through the muscular coats of the bladder on either side, and held up. The end of the catheter being pointed between these sutures, an incision was made upon it into the bladder large enough to admit a finger. Lithotomy forceps were introduced, and a small mulberry calculus extracted without difficulty. The whole was then carefully cleansed. Three catgut sutures drew the edges of the bladder wound into close apposition. Catgut sutures similarly brought together the separated recti muscles, and catgut was used to close the superficial wound, with the exception of the upper part, where a drainage-tube was placed. The wound was dressed with iodoform, and iodoform gauze with salicylic wool was employed to cover all. No catheter was left in the bladder. Six hours after the operation, the patient had vomited at intervals. As no urine had been passed, a catheter was introduced, and an ounce of blood-stained urine drawn off. Temperature 98·8°.

[1] THE LANCET, vol. i., 1886, p. 714. [2] Ibid., p. 740.

Aug. 1st.—At 4 A.M. two ounces of blood-stained urine were passed naturally. Throughout the day he has passed urine five times, in all ten ounces. There is no blood in the urine. Vomiting ceased. Temperature, 8 A.M., 97·8°; 12 P.M., 95·2°.

2nd.—Still passing his urine naturally; no blood in urine. 3 P.M.: Dressed under the carbolic spray. The wound had united by first intention, without any pus being formed; the tube was therefore removed and the wound re-dressed. Temperature, 8 A.M., 99·4° (the highest temperature recorded).

4th.—Wound again dressed; sutures removed. It is perfectly healed; patient, as previously, passing urine without difficulty, eight ounces in the twenty-four hours.

7th.—The child is now well, sitting up and playing about as if no operation had been performed. The temperature is normal.

The patient was kept in the hospital under observation until the 18th, but was then discharged, as there had been no symptoms, and the cicatrix continued firm and painless.

Remarks by Sir WILLIAM MAC CORMAC.—I think few surgeons perform the lateral operation for the removal of a stone from the male bladder without feeling some anxiety. In children, although very successful, there are some special risks attending the operation, and one certainly is that the bladder may not be reached at all. The parts are very small, easily torn, and may readily enough yield before the finger when the latter is being pushed into the bladder after incision of its neck. Another liability in the male child is the emasculation of the subject of operation. I well recollect how very strongly Langenbeck insisted on this being by no means an unfrequent result of the lateral method in the child. Indeed, he always performed the high operation in children, and his teaching was very generally adopted in Germany. It appears to me that the restriction of the high operation to the removal of very large stones is likely to be shortly modified in favour of a wider extension of this method. In no case would it seem more applicable than to those of children, in whom the bladder is naturally high and easy to reach, the urine fairly normal and unirritating. The case above narrated proves that immediate union may follow, with absolute absence of general disturbance, pain, or distress of any kind. The wound was soundly cicatrised within a week, and the boy in perfect health. I advisedly abstained from employing the catheter, which is an evil in itself. The urine required to be only once drawn off after the operation. The case, in short, is a parallel one to that of Mr. Parker's, reported in THE LANCET of July 3rd. But he is not quite correct in believing his to be a unique case, for three similar ones of primary union after supra-pubic lithotomy were lately reported in the *Deutsche Centralblatt für Chirurgie*. A result such as the foregoing is well worth recording, and is certainly as nearly perfect as any surgical proceeding can well be. As experience of this rehabilitation operation grows, its value and scope will become more and more strictly defined; yet even now it would seem a desirable plan to follow in the case of young children.

BOROUGH HOSPITAL, BIRKENHEAD.

CASE OF POISONING BY PHOSPHORUS PASTE; DEATH ON THE FIFTEENTH DAY: NECROPSY.

(Under the care of Dr. HARRIS.)

THE report of this case is furnished by Dr. H. E. Richardson.

William S——, aged thirty-two, ship's steward, a well-built, muscular man, about 5 ft. 10 in. in height, was brought to the surgery, at 9.45 P.M., on June 12th, 1886, by a police-constable, who stated that the patient had handed him in the street a pot of phosphorus paste (Roth and Ringeisen's), and said that he had taken it with the intention of committing suicide. A threepenny pot was produced, which would hold about half an ounce of paste. A great quantity of this appeared to have been taken out with the finger. The patient stated that it was not more than half an hour since he had swallowed the poison, and that he took it on account of some family trouble. He seemed in great distress. The stomach-pump was at once used and the stomach washed out with five or six basinfuls of warm water. Lastly, three grains of sulphate of copper were mixed in a pint of warm water and given to him to drink. It was immediately vomited.

Digitized by Google

On admission he was ordered a hot bath, and placed in a private room in custody of a police-officer; to have a diet of milk, and the following mixture every four hours: carbonate of magnesia, ten grains; sulphate of magnesia, one drachm; peppermint-water to one ounce. His pulse was normal, and he said he felt comfortable. The pailful of fluid which had passed in and out of the stomach was then examined. It had a strong smell of phosphorus, and was luminous in the dark.

June 13th.—11 A.M.: Temperature 98·6°; pulse 80 per minute. Slept all night. Bowels open once freely. Complains of a curious sensation down his throat.—11 P.M.: Temperature 97°; pulse 66. Vomited three times to-day—on the first two occasions bile-stained fluid, then curdled milk. Bowels open again freely; motions loose, and of a dark-brown colour. The mixture discontinued. Ice given to suck. Patient seems low-spirited, but does not show any symptoms from the effects of the phosphorus.

14th.—11 A.M.: Temperature 98·7°; pulse 50. Did not sleep so well last night. Bowels open again this morning.—11 P.M.: Temperature 98·8°; pulse remarkably slow, only 46 per minute. Vomited three or four times to-day after taking milk. Had one dose of the magnesia mixture this evening. No pain or tenderness in abdomen. Lies comfortably in bed. Bowels were open this evening; motions loose, of a dark-brown colour, and very offensive.

15th.—11 A.M.: Temperature 99·2°. Slept at short intervals during the night. Vomited twice some watery fluid mixed with mucus and slightly tinged with blood. Ordered an ounce of castor oil.—11 P.M.: Pulse 66. Bowels open three times after the oil. Has vomited some of the milk he has been taking. A hypodermic injection of morphia (a quarter of a grain) given.

16th.—11 A.M.: Temperature 97·6°. Did not sleep after the morphia injection last night. Vomits the milk he takes, which is curdled. Bowels open once last night. Slight jaundice noticed to-day in the conjunctiva. Ordered two drachms of tincture of opium in eight ounces of water every six hours. The urine is of a dark red-brown colour, due to bile-pigment; acid; sp. gr. 1020; no albumen.—11 P.M.: Temperature 101·2°. Pulse 68 per minute. Vomiting continues; perspires profusely. Did not sleep all night. Complained of pain in the abdomen, but felt relieved after each action of the bowels, which were opened three times, motions being light-coloured.

17th.—11 A.M.: Temperature 98°. Pulse 96. Jaundice more marked to-day, especially on face and chest; face also looks flushed. The tongue is more or less furred. Liver dulness normal, but there is some tenderness over it. Lies with legs drawn up. Complains of a burning sensation all over, especially of face and head. Throws off bed-clothes. Vomits frequently curdled milk and a watery fluid; no bile in it. Has been very restless all night. Ordered tincture of rhubarb, six drachms; carbonate of ammonia, half a drachm; bicarbonate of soda, two drachms; water to eight ounces: an ounce to be taken every six hours.—11 P.M.: Temperature 100·1°. Pulse 70. Passed forty ounces of urine, of a brownish-black hue, in the twenty-four hours. Took one pint of arrowroot, half a pint of beef-tea, and two pints of iced milk to-day. Vomited the arrowroot only. One-third of a grain of morphia given hypodermically.

18th.—11 A.M.: Temperature 98·6°. Slept four hours last night. Bowels open once freely; motions very foul, and like chalk-and-water. Took two pints of iced milk during the night; vomited three times. Any movement after taking the nourishment seems to excite the vomiting. Urine is of a reddish-brown colour; sp. gr. 1026; no albumen; no sugar. 11 P.M.: Took arrowroot, beef-tea, and iced milk to-day. Vomited twice only some half-digested food; no bile. Temperature 99·6°; pulse 80; respiration 28 per minute. Bowels open once; of a light clay appearance. One-third of a grain of morphia given hypodermically.

19th.—11 A.M.: Temperature 99·2°. Slept for four hours after the morphia injection. Bowels opened once freely; motions foul, like chalk-and-water. Took two pints of iced milk; no vomiting. Intensity of jaundice increased, and is assuming a brownish tint; tenderness over liver on percussion.—11 P.M.: Temperature 100·4°. Took two pints of iced milk and some tea and toast to-day; no vomiting; has a slight cough. A hypodermic injection of morphia, one-third of a grain, given.

20th.—11 A.M.: Temperature 99·2°. Slept well last night; awoke only twice, and had some iced milk. Bowels open once; light coloured motions. No vomiting.—11 P.M.: Temperature 100·2°; pulse 80; respiration 20. Took two pints of iced milk, half a pint of beef-tea, and half a pint of arrowroot to-day; no vomiting. A ten-grain mercury pill given to-night. The mixture to be continued as before.

21st.—11 A.M.—Temperature 98°; pulse 84; respiration 24. Slept at short intervals last night; slightly delirious towards morning, attempting to get out of bed. Bowels opened twice, white as before. Has had iced milk. There is an inclination to vomit, though he has not done so. No pain, but he seems depressed. Is intensely jaundiced; eyes look sunk, and there is a dark rim around each orbit.—11 P.M.: Temperature 98·8°; pulse 76; respiration 24 per minute. Has had three pints of iced milk and a pint of beef-tea to-day. No vomiting; bowels opened three or four times, and had the appearance of chalk-and-water.

22nd.—11 A.M.: Pulse 88; respiration 20 per minute. Very restless during the night; dozed at times; was delirious and attempted to get out of bed; is in the same state this morning. Refuses nourishment, and is with difficulty made to take it. No vomiting. Bowels not opened. Catheter had to be passed and urine drawn off. Medicine discontinued, and a hypodermic injection of a quarter of a grain of morphia given.—2.30 P.M.: Vomited twice after some beef-tea, given with a spoon with difficulty, the only nourishment since morning. A round worm (Ascaris lumbricoides) six inches long was found in the vomited matter. Brand's essence of beef ordered in small quantities.—6 P.M.: Vomiting continues. One grain of opium pill given, dissolved in a teaspoonful of water. Linseed-meal poultices to the abdomen.—11 P.M.: Pulse 84; respiration 12 per minute (Cheyne-Stokes'). The beef essence retained since pill was administered. Catheter passed, and urine drawn off. A quarter of a grain of morphia injected hypodermically.

23rd—11 A.M.: Pulse 80. Respiration 6 per minute (Cheyne-Stokes'). Dozed at short intervals after the morphia injection; quiet all night. Took two pints of iced milk, together with the Brand's essence of beef in small quantities. Vomited four times; passed urine once. The morphia injection was repeated and the following mixture was ordered: one drachm of pepsine (B.P.); one drachm of dilute hydrochloric acid; four drachms of syrup; eight ounces of cascarilla infusion: one ounce every four hours.—11 P.M.: Pulse 88. Respiration 8 per minute (Cheyne-Stokes'). Urine drawn off with a catheter. It was very dark, bile stained. Perspires profusely. Has taken Brand's essence of beef and iced milk in small quantities during the day. No vomiting. Bowels not opened for two days. Ordered an oil enema, but it was immediately returned without having effect. Patient is quite prostrate and takes very little notice.

24th.—10 A.M.: Temperature 99°; pulse 94; respiration 8 per minute (Cheyne-Stokes'). Slept at intervals. Nourishment given in small quantities with a spoon. Complete prostration and stupor. Perspires profusely. Catheter passed and urine drawn off. Another oil enema given, which acted.—12 noon: Temperature 99·7°.—8 P.M.: Temperature 100·6°; pulse 120; respiration 26 per minute. The pulse and respiration have gradually increased since the morning. Brand's essence of beef and iced milk given in small quantities during the day.

25th.—9 A.M.: Temperature 102·2°; pulse 124, full, bounding; respiration 28 per minute, stertorous. The stupor is passing into coma. Sweats excessively. Motions and urine passed involuntarily. No vomiting.—12 noon: Temperature 102°.—3 P.M.: Temperature 102·4°.—8 P.M.: Temperature 102·6°; pulse 132; respiration 32, stertorous.—11 P.M.: Temperature 103·8°; pulse 132; respiration 44, stertorous. Is in a state of profound coma.

26th.—1.30 A.M.: Temperature 105°; pulse 150; and respiration 54. Has been fed with small quantities of Brand's essence of beef.—2 A.M.: Temperature 105·2°. The circulation is enormously quickened; the pulse cannot be counted. He remained in this state of coma until death.—3 A.M.: Temperature 106°.—3.30 A.M.: Temperature 106·4°.—4 A.M.: Temperature 107°; respiration 60 per minute, stertorous.—4.30 A.M.: Temperature 107·4°.—5 A.M.: Temperature 107·8°; respiration 42 per minute, stertorous.—6 A.M.: Temperature 108·2°.—6·30 A.M.: Temperature 108·6° five minutes after death.

The necropsy was performed by Dr. Richardson, on June 27th, thirty hours after death, and the condition was as follows: Well-nourished, muscular man. Skin deeply jaundiced (a brownish-yellow colour). The lungs on section had a black tarry appearance, and, on pressure, thick, dark, frothy

Digitized by Google

blood mixed with minute oil-globules, oozed out. The heart weighed 13½ oz., and was very soft and flabby; its outer surface had a pale reddish-yellow appearance. The endocardium and the inner coats of the large arteries were of a mahogany colour, deeper staining being noticed here and there. The liver was much diminished in size, weighing only 42¾ oz., of a drab mottled appearance, very soft and flabby, with thin edges, so that it could almost be rolled up. It was greasy-looking. On section, it was found to be of a uniform brownish-yellow colour, bloodless, with abundance of free oil-globules. The gall-bladder contained a little thin greenish fluid. The kidneys (right weighed 8 oz. and the left 7¾ oz.) were very soft, and their capsules were loosely attached, so that they were easily peeled off, and on section had a pale and oily appearance. The spleen weighed 5¾ oz., and its substance was soft and of a tarry and oily appearance, like the lung. The stomach contained some fluid nourishment mixed with mucus; its coats had the general yellowish altered appearance, but no erosion or congestion could be observed. The brain was not examined. A microscopical examination was made of the organs, and they were all found to have undergone fatty degeneration. The most marked of all was the liver; its cells had disappeared more or less completely, and in their places were observed separate globules of oil, studded all over. The muscular fibres of the heart had lost its striated appearance, and were covered with minute molecules of oil. Extensive fatty change was noticed in the granular epithelium of the kidneys. All these sections for the microscope showed the deep brownish-yellow bile staining markedly.

Reviews and Notices of Books.

Paralyses—Cerebral, Bulbar, and Spinal: a Manual of Diagnosis for Students and Practitioners. By H. CHARLTON BASTIAN, F.R.S. London: H. K. Lewis. 1886.

IT may at first sight seem peculiar that "paralyses" should form the subject of a work on diseases of the nervous system designed to teach the student and practitioner the art of making a diagnosis. But a little reflection will show how it is possible to collect under one heading so much information as Dr. Bastian has been legitimately able to do in this his latest and not least important work. Yet it must not be supposed that the volume before us is an exhaustive one on diseases of the nervous system, though we are bound to confess that the department with which the author deals is by far the most interesting, as it is the most difficult, field of investigation.

There are two chief ways of writing a book of the kind under consideration—the analytical and the synthetical. Dr. Bastian adopts a fairly judicious mixture of the two. He does not everywhere give chapter and verse for the inferences at which he arrives, but he does this wherever matter of a specially controversial character is under discussion. To the earnest student there is much advantage in this arrangement, but to the busy practitioner a general or synthetical statement would probably be more acceptable. To a man of Dr. Bastian's position and learning in neurological matters, to say that the book contains nothing that is unorthodox might be irrelevant, were it not for the fact that even in its alphabet neurology is not a settled science. On the important subject of myelitis Dr. Bastian writes, "that he is far from denying that a primary inflammation may involve areas of the cord and entail softening of its substance," though he rather suspects that most inflammations are of a secondary nature and due to some tangible irritation. We think there is a little over-cautiousness in these views. We have no doubt of the occurrence of primary myelitis. Whether softening of the substance of the cord occurs or not should be regarded as of the nature of an accident, hardly calculated to throw light on the pathology of the morbid process. But it may be asked whether there is any essential difference between primary and secondary myelitis. A primary myelitis must have a cause which may be regarded as an irritant. Many cases of infantile palsy are due to the occurrence of a primary myelitis, the causation of which is of the most obscure kind.

It is a feature of the author's mind—and this book bears admirable testimony to the fact—that anything of a mysterious nature finds no favour in his eyes. Dr. Bastian is gifted with a far-seeing and penetrating intellect, and he accepts new facts slowly, not from a want of capacity to understand the bearings of fresh matter, but because novelty to his mind is no recommendation. No one can discern in this book traces of Dr. Bastian's well-known former hostility to the value of the state of the so-called "deep" reflexes. His acceptance and appreciation of their value in anatomical diagnosis of the morbid conditions in the spinal cord is at once complete and just, for he expects neither too much nor too little from their aid. The arrangement of the book must be acceptable alike to the diligent and to the busy; it is systematic without being arid, and helpful to the student without being inaccurate, as so many attempts with a view to assistance in acquisition are liable to be. With the aid of heterogeneous letterpress the author has done what he could to separate the less important from the principal matter.

A valuable chapter (though what many students will probably find hard reading) is devoted to a consideration of the physiology of speaking, reading, writing, and thinking; being some account of the nature and order of the cerebral processes involved in these acts. The article on the sense of movement, or kinæsthesis, will be read with profit by the advanced student and physiologist; the views expressed therein are practically identical with those given by the same author in "The Brain as an Organ of Mind"—a repository which we venture to think far more suitable for their expression than a work professedly concerned with teaching the student the art of practical diagnosis. Many readers may be of opinion that there are too many digressions from the main drift of the book of the like nature to that which has called forth our comments; whatever of justice there may be in such criticism, it must be owned that without some appreciation of the high physiology of the central nervous system anything like a full understanding of its bearings on the diagnosis of obscure cerebral conditions is not likely to be attained. We can strongly recommend Dr. Bastian's work to the student and practitioner as a monument of learning, exceedingly well put together.

The Management of Labour and of the Lying-in Period. A Guide for the Young Practitioner. By HENRY G. LANDIS, A.M., M.D., &c. Philadelphia: Lea Brothers and Co. 1885.

THIS book aims at giving practical instruction to the young medical man embarking in practice; it does not profess to be addressed to students. It is, however, one of those books the production of which does not seem to us to have been required in the interests of anyone. A student forming himself on the instructions here given would certainly be rejected at any good examining board, not only on account of imperfect information, but also on account of the errors which would be imparted to him; but to the practitioner who followed its advice the consequences might be more serious, both to himself and the patient. It is only fair, having said thus much, to give some reason for our opinion.

We will begin at the beginning. On page 14 we are told that "very little pain attends the contractions unless disease of some sort has interfered with the proper action of the parts concerned. There should be no pain at all during the first stage." About what country is our author speaking? About America? Is it true that American women have this immunity? Does it apply to immigrants, or only to those who have descended from naturalised parents?

Digitized by Google

But the second sentence in our quotation shows that this may not be our author's meaning, but merely that pain in labour is pathological. Experience tells strongly against this view; indeed, the language of all nations applied to the pains of labour speaks the contrary with no uncertain voice. This idea is continued on the next page, where we read that, "if a woman has a markedly painful labour, it is because personal or inherited violation of hygienic law has caused her to be afflicted with inflammation or mechanical disabilities in the organs of parturition, and not because it is natural for women to suffer in childbirth." Again, we read on page 17 that six hours is the "maximum limit of normal labour." All these statements are not only entirely without foundation, but contrary to known facts. "It is painful to admit that, notwithstanding the teachings and practice of the best obstetricians, and the near approach of obstetrics to a science, there is a widespread tendency to non-interference." We are compelled in the interests of truth to point out that this statement betrays want of acquaintance with the history of midwifery, which has shown a steady progress in the other direction, and has exemplified the words of the Prophet that, in the vast majority of cases, "our strength is to sit still." Our author is quite honest in his opinion, and the words, "the strong delusion ..... that meddlesome midwifery is bad," set it forth even more plainly than we have done (page 19). On page 47 we read: "When once the head begins to press upon and stretch the perineum, the tonicity of the perineum is directly impaired by every degree of continuance of the labour. The longer the time taken to distend it, the more its circulation is impeded and its powers of cohesion diminished." This is not correct; nature provides gradual dilatation as the best safeguard, and the good practitioner endeavours to compass the same end.

We now come to a different category of statements—namely, those concerning the estimation of the conjugate. On page 94 we are told that after measuring the external conjugate "we then guess how thick the sacrum and dorsal tissues are, and how thick the symphysis must be, and deducting these measurements we can guess how long the conjugate diameter is, which might have been done without so much trouble in measuring. ... ... When we succeed in touching the promontory we note exactly where the anterior vulvar commissure touches the skin of the hand. From this point to the finger tip we measure, and this will give us the diagonal conjugate (Fig. 8). Since the inner face of the symphysis is perpendicular, we have the hypothenuse of a right-angled triangle." Exception may well be taken to this passage, not only on the ground of its inaccuracy but the style of its composition.

In a book dealing with midwifery no part is more important than that concerning the department of hæmorrhage. On this subject much that is valuable may be read in any old treatise on midwifery, while late years have added much to our knowledge both of its pathology and treatment. Of the digestion of knowledge, ancient or modern, we here find no trace. Hot milk is said to be the best drink after hæmorrhage, "because it is a near approach to blood" (page 165). We are surprised that our author does not plainly recommend black puddings if this is the reason. In the same place we read that a woman never dies of post-partum hæmorrhage except from neglect, "so certain is our control in these matters." Our author has been, perhaps, fortunate, but he has not apparently read of cases in which hæmorrhage has been absolutely uncontrollable in spite of the most careful treatment. Such cases are indeed very rare, but are none the less undeniable. Dr. Landis seems to think (page 167) that by the hypodermic injection of whisky the volume of blood lost can be restored. "It is possible that enough fluid can be thus injected," &c.

Rupture of the uterus is treated in half-a-dozen pages, and in a most inefficient manner. The chapter on septicæmia is not only inadequate, but positively dangerous, since ridicule is thrown on the idea that septic poison can be introduced from without.

We have now ended our irksome task. To praise is both pleasanter and easier than to find fault; but a reviewer has the serious responsibility of helping others to "eschew the evil" as well as to "choose the good"; and "butter and honey" may enable him to do one, but cannot help him to do the other.

A Short Manual of Chemistry. Vol. I.—Inorganic Chemistry. By A. DUPRÉ, Ph. D., F.R.S., F.C.S., &c., and H. WILSON HAKE, Ph.D., F.C.S., F.I.C., &c. London: Charles Griffin and Co. 1886.

THE authors tell us in their preface that they believe "that the very multiplicity of text-books already published tends to show a want felt, but not yet satisfied." We cannot entirely agree with this; for elementary text-books are multiplied for several reasons, among which the most important is that no two teachers have exactly the same ideas as to the best mode, and each wants a book which harmonises with the arrangement of his own lectures. There are, in truth, at the present time many—perhaps too many—excellent elementary manuals, and the teacher finds it difficult to choose between them. Among these excellent books we shall in future reckon that of Drs. Dupré and Hake; for though there is but little attempt at originality in it, it is lucid and simple, and gives a good account of modern chemical theory and fact. The physical considerations which have affected chemistry so profoundly are explained with somewhat unusual fulness and in clear language, and the accounts of the elements and chief compounds are succinct without being too meagre. The chief point in which the book differs from other recent ones is that the authors have followed the lines adopted by Graham in his now antiquated, but in its time inestimable, treatise. They hold that the broad principles of the science should be studied first, with as little reference to details as possible. Teachers differ much in regard to this question, many preferring to plunge at once into the facts of chemistry and bring out the theories little by little afterwards. Personally we prefer the system used by Graham, believing that students who follow it acquire a broader view of chemistry as a whole, and approach the more practical part of their studies with greater intelligence than those whose theoretical training has been more fragmentary. It must be remembered that in a science like chemistry it is more important to understand general truths than to remember individual facts. It is a common complaint among students who have passed through a stiff examination, that they begin to forget the facts as soon as the examination is over, and they infer that therefore their training has been useless. This is a very obvious mistake. If the training in general principles has been sound, the mere forgetting of details does not destroy it. None of us can remember a thousandth part of the facts we have learnt, but if we have been well trained we can take down a book and understand it, and so find, perhaps, in a few minutes the facts we may require.

Returning for a moment to the text-book before us, we may remark that it is on the whole accurate, and has evidently been carefully prepared. But of course there are some slips. Of these the most important is in the table of elements given on pages 64-5. The column headed "molecular symbol" is most misleading. In the first place, the correct phrase is, of course, "molecular formula"; but, what is of far more importance, many formulæ are given in the column for which there is absolutely no evidence whatever. How, for instance, can we possibly tell that the molecular formula for chromium is Cr_2, and its molecular weight 104·8?

Vital Statistics: a Memorial Volume of Selections from the Reports and Writings of William Farr, M.D., D.C.L., C.B., F.R.S. Edited for the Sanitary Institute of Great Britain by NOEL A. HUMPHREYS, of the Registrar-General's Office, Member of the Council of the Statistical Society of London. London: Edward Stanford.

IT is difficult in a notice of the volume before us to refrain from discussing the works of Dr. Farr himself, for probably no writer of the present century has done more to make records of mortality a means of preventing that mortality, or to confer benefits upon mankind by enabling proper provision to be made against the accidents to which all human life is exposed. Dr. Farr's studies have contributed in an untold degree to our knowledge of etiology of disease. He has enabled life assurance to be placed on an equitable basis, and may indeed be said to be responsible for our Post-office insurance. A strong believer in the teachings of figures when properly handled, Dr. Farr made the utmost practical use of the facts which they indicated. No better evidence of this can be given than will be found in his report upon the mortality from cholera in England in 1848-49, and his subsequent reports upon the epidemics in 1853-54 and 1865-66, when he showed, at any rate to the satisfaction of English observers, the part played by pollution of drinking-water in the dissemination of this disease. But perhaps the works with which his name will be best associated in the future are his Life Tables published in the Registrar-General's annual reports. Most of his writings necessarily appear in the official records of this department, but others of great value occur elsewhere, particularly in the Transactions of the Statistical Society.

The Sanitary Institute has done public service in making Dr. Farr's work more available for general use, and especially in entrusting the important duty of selecting and editing his writings to his friend and colleague Mr. N. A. Humphreys, whose own distinguished position as a statistician, and whose long association with Dr. Farr will enhance the value of the volume in the opinion of its possessors. Mr. Humphreys has divided the book into six parts, and has grouped Dr. Farr's chief writings under the headings Population, Marriages, Births, Deaths, Life Tables, and Miscellaneous, and has himself written a few introductory pages to each part. Each introduction is followed by an exceedingly well arranged series of extracts from Dr. Farr's writings, and at the end of the volume will be found a copious index, which adds much to the usefulness of the book for purposes of reference. To the student of public health and social problems, "Vital Statistics" will be a welcome visitor and a useful friend, while it is in every sense a suitable memorial to Dr. Farr. Perhaps no higher praise can be accorded to it than to state that, in its arrangement and compilation, it is worthy of the editor to whom this duty has been entrusted.

Analytical Records.

CASSELL'S CEYLON TEA.

THE tea plantations of Ceylon have been a great success, and have added in an important degree to the material resources of the island. The sample now before us is very satisfactory. There is no facing or other mineral matter. The leaves are small and clean, and give a strong decoction of delicate flavour. Such tea may well replace the product of China.

SELLERS' NAPHTHOL SOAP.

(J. H. SELLERS, FARRINGDON-ROAD, LONDON.)

Naphthol is a crystalline, sparingly soluble compound, which bears to naphthalene the same relation as phenol (carbolic acid) does to benzene. Its use in eczema and other skin diseases has lately been advocated; and as it is not unpleasant in smell and possesses some antiseptic power, it deserves careful trial. In the present preparation the naphthol is incorporated with a clear and easily soluble potash soap, which is pleasant to use. The naphthol can easily be detected by acidulation and distillation with water. It comes over and condenses in needles.

MARSHALL'S CORN PREPARATIONS.

(J. & T. MARSHALL, GLASGOW.)

Messrs. Marshall have already several excellent preparations in the market, and here are several useful variations. *Farola* is a beautifully clear and very finely divided semolina. It breaks readily into cells with water, and the microscope shows that it is pure wheat. *Granola* is similar to the last, but contains the finer husk of the wheat, and is therefore a kind of whole-meal semolina. It is quite free from adulteration, and is a very useful and nutritious food, especially to those who suffer from constipation. The *Oat Flour* is correctly described by its name. It is a fine cream-coloured flour, containing all the gluten and oil of the grain, and no husk.

CALVERT'S TWENTY PER CENT. CARBOLIC MEDICAL SOAP.

This well-known and valuable article is now made up in small sheets, of which a packet takes almost no room in the pocket. They will be very valuable to the physician and for occasional household use.

BROOKE'S SOAP.

This soap, which is specially recommended by the proprietors for cleaning and polishing metallic vessels in ordinary domestic use, we have found very useful in the cleaning of surgical instruments. It does not answer satisfactorily in the case of knives, as the gritty material in its composition spoils the edge, but for forceps and other instruments not of a cutting character it answers admirably. In cleaning these, it is better to depart from the plan proposed in the directions given, and use the soap dry, scraping some of it on to a "buff-stick"—that is, a piece of wood shaped like a razor-strop, to which a strip of buff leather has been fixed down one side, and then rub the instrument on this. It is very effectual in removing dirt and recent stains, at the same time giving a good polish.

ST. MARY'S HOSPITAL.

WE are gratified to learn that the Residential College for Students, connected with St. Mary's Hospital, which was instituted only twelve months since, has been a great success. Already the School Committee have found it necessary to double the accommodation originally provided. "The College is under the supervision of a warden, who, with a lady superintendent, resides in the building." In this way medical students, fresh from hearth and home, receive such care as is conducive to their health, comfort, and happiness. There is discipline, but it is not harsh. There are supervision and direction, but the reins of guidance are gently handled. From a prospectus recently issued by the governors of St. Mary's, we learn that the medical school buildings, which were enlarged at heavy outlay three years ago, are inadequate to the present call upon them. A new wing is in course of erection. This will add to the space already allotted to various departments, and, in addition, will provide a spacious laboratory for bacteriological and special pathological research. The drainage and sanitary fittings of the hospital are undergoing complete reconstruction. This high-spirited policy deserves success, and doubtless will command it.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 25, 1886.

IT seems desirable that the attention of the Secretary of State for War should be specially called to a serious defect which exists in the administration of the Army Medical Department. We allude to the want of any recognition of the services of the officers, however valuable these may be, unless they are rendered in the field with troops. We are far from underrating the value of the latter, either from the life-saving point of view, or from the equally important moral influence upon the men arising from the knowledge that skilled aid is at hand if they are wounded; but we attach at least as much importance to the professional work involved in the treatment of widespread epidemics, and to the mental labour required to devise and carry into effect those sanitary measures which are necessary to promote the health and efficiency of the soldier in peace as well as in war, and to prevent outbreaks of disease which are far more fatal in their effects than the artillery or rifles of an enemy. Yet in the distribution of rewards and honours such services, when rendered by army medical officers, are systematically ignored. This treatment is not extended to other departments of the army, for if we examine the lists of the Order of the Bath, we find among the Civil Companions officials of all grades, from general officers to War Office clerks, but not a single army medical officer. Among these names are many well known in the scientific world, nor would we for a moment imply that the others have not also earned the coveted distinction by valuable and honest service; but we protest against the omission of medical officers who have claims, scientific and professional, equal at least to those of a large number of the decorated. We know not to what their exclusion from a share in such honours may be attributed, but it certainly is not to any lack of officers who have clearly earned a title to them; nor is it due to neglect on the part of the head of the department to bring such services under notice, for it is within our knowledge that directors-general have recommended officers for this distinction on such grounds, and that their recommendations were not carried into effect. The army reports and the report of Lord HERBERT'S Commission furnish us with some remarkable evidence as to the value of the sanitary services rendered by the army medical officers. For instance, among the troops serving at home the death-rate on the average of the ten years 1837-47 was, among the cavalry 13·5, foot guards 20·4, and infantry of the line 17·8 per 1000 of the strength, while on the average of the ten years 1874-83 the ratios were 4·45, 5·37, and 4·76 per 1000. On foreign stations the reduction has been still more striking; in the West Indies the ratio has fallen from above 80 to under 16, and in India from over 60 to about 17½ per 1000 on the average of ten years. We leave it to the War Office actuary to determine the saving of life and of money resulting from these great reductions. We do not say that this has been effected by sanitary measures alone, but there can be no doubt that they have been a most potent agent. We have been unable, after careful inquiry, to find that any one of the officers by whose skill and labour these important results have been achieved has ever received any reward or had any honour conferred on him in recognition of them. That such treatment should be possible is far from creditable to our War Department, and we trust Mr. W. H. SMITH will take early measures to remove and, for the future, to prevent it. It appears to us that under the present system the selection of medical officers for honorary distinctions rests with the military authorities, who are not competent to judge of the value of professional services, while the head of the department, who is in every way qualified to do so, is ignored, and, if he ventures to make a recommendation on such grounds, has the mortification to find it disregarded. It surely is not too much to expect that the recommendation of the Director-General to reward valuable professional services in an adequate manner should meet with more consideration than in the past, and that rewards should be conferred for services other than those in the field. From a public point of view, it is most desirable that the army medical officer should never forget the importance of the duty of maintaining the health and efficiency of the men entrusted to his care; but it is almost too much to expect of him, when he finds his services in that direction ignored, and his labours, however valuable, overlooked in the distribution of rewards. A serious evil resulting from this system is that the administrative medical officer is disposed to look upon these important duties as mere matters of course, and, as in an instance quoted by "A Surgeon, Medical Staff," in *The Times*, instead of giving credit to an officer for long and zealous professional service rendered under circumstances of difficulty, to content himself with the congratulatory remark, "It is lucky you did not get ill yourself." It redounds to the honour of the medical officers that, with a full knowledge of the neglect with which they would be treated, they have persevered in a course which has proved so beneficial to the soldier, and has assisted in a very important degree to promote sanitary science and its practical application to public health.

THE appearance of Sir SPENCER WELLS as President of the Sanitary Institute of Great Britain during its recent congress at York was altogether congruous and satisfactory. Only superficial persons would think sanitation a subject of little interest to surgeons; in truth, their interest in it is almost terrible, and their splendid contributions to it of late years—notably those of SIMPSON, LISTER, WELLS, and TEALE—have been most valuable and significant. The difference between modern surgery and old surgery is chiefly one of sanitation. The worst accidents and calamities of old surgery were not due to the coarseness of its instruments or the unskilfulness of its operators, but to subtle impurities of air and water, to impalpable and invisible germs, whose influence has now been well-nigh checked and counteracted, thanks to the care and the methods of modern surgery. Sir SPENCER WELLS kept this particular aspect of the question of sanitation in abeyance at York, but there is no reason why we should treat it with such modesty; on the contrary, we

Digitized by Google

magnify the merit of our great surgeons in this branch of hygiene, and see in their labours and their successes the most triumphant demonstration of the virtues of pure air against all champions of traditional filth and carelessness.

Sir SPENCER WELLS, with much good taste, took a broad survey of his subject, regarding it rather from a public point of view than from his high professional position. His main contention, indeed, was this, that in respect of sanitation the scientific and professional work has been largely done; at any rate, that the cause of public health suffers now more from want of the help of proper legislation and effective administration than from want of scientific data to go upon. He does not fail to notice the present impotence of Parliament. "The waste of time and energy in Parliament in party struggles has banished all possible home legislation." These are wise and grave words from one above all party considerations, and, as the whole spirit of his address shows, with a generous and charitable feeling to all classes of workers, from workers with the hand to legislators and ministers of the Gospel. It is well that our legislators should know how their work, or rather their want of work, is regarded by a man of action, and of evidently broad political feeling. He sees national work to be done that is not being done. Everything has a special Minister but the health of the people, and this is sacrificed to considerations of economy. It is not sensational enough. It does not affect "party struggles." That a man should have a vote, and that he should be able to vote by ballot are evidently prime desiderata; so it is that he should have plenty of cheap bread, especially as a rival set of politicians are interested in its being dear. But that he should have pure water and plenty of it, that his house should be decent and his work harmless, that the air he breathes should be uncontaminated, that his life should be protected from the onslaughts of insidious and impalpable germs in his milk, or his clothes, or his pork—these are points out of which the most astute party leader can extract no enthusiasm. And so the cause of health languishes, and many diseases flourish.

Sir SPENCER WELLS is not a complainer; he is cheerful even under the depressing circumstances of a Government very indifferent to health questions as compared with party questions. He anticipates a good time coming; when the crisis of angry discussions and political complications has passed, the turn will come for practical measures. What a fine faith there is in a sentence like this! His estimate of progress, too, is a generous one. Human life has been lengthened twenty years by the labour of sanitarians, chiefly medical men, in the last half-century; the people are more thrifty, and when they are ill they are better looked after under provident medical arrangements; drunkenness and crime have diminished. There is a broad statesmanlike tone in Sir SPENCER'S treatment of such questions as school-pressure and the mental and physical training of women. He thinks women capable of a great deal more than they have been accustomed to do in times past. As regards school-pressure, he does not deny it, but cleverly connects it with the very success of sanitarians. Such children as exemplify it in less perfect times would have been effectually killed before the school age by bad sanitary conditions; now "they are survivals of the least fitted." They must be trained more and taught less. The specific points urged by Sir SPENCER WELLS on his audience were all good, though somewhat miscellaneous, having reference to the education of children, the cultivation of forests by governments, the prevention of disease, and the support of hospitals and convalescent homes. On one favourite topic he repressed himself—that of cremation; but his whole address was eminently worthy of one who has added greatly to the health and happiness of human life.

MATTERS connected with the physiology and pathology of the larynx are in an unsettled state. We are in a position to make several positive assertions on the subject, but how to completely reconcile all the statements it is not easy to discover. The propositions that may be made are as follows: 1. Stimulation of the recurrent laryngeal nerve by a strong faradaic current gives rise to adduction of the vocal cords, provided that the animal (dog or monkey) be not too deeply narcotised. The same adduction of the vocal cords is observed if the stimulation be applied to the recurrent nerve of the recently excised larynx. 2. Stimulation of the recurrent nerve with weak currents, however, usually causes abduction of the vocal bands. 3. It is maintained (SEMON'S theory so called) that the abductors of the larynx are weaker than the adductors, or rather that in all cases of acute or chronic organic disease or injury of the nuclei or trunks of the motor laryngeal nerves (spinal accessory, pneumogastric, recurrent laryngeal) the abductor muscle or muscles first succumb, whilst, on the other hand, in cases of functional disorder the adductors usually suffer alone. 4. Experimental injury to the whole trunk of the recurrent nerve is followed after a few days by histological changes of a fatty order in the fibres of the abductor muscles, the adductor fibres not apparently suffering.[1] 5. GRÜTZNER and SIMANOWSKY declare that there are histological differences between the adductors, which belong to the group of "white" muscles, and the abductors, which are members of the group of "red" muscles. 6. The abductor muscles "die" sooner than any of the adductors; they lose their electrical irritability earlier than their antagonistics; and yet the abductor posterior crico-arytenoids are absolutely the most bulky muscles of the larynx. 7. The larynx contains muscles of organic life that subserve respiration—the abductors; and muscles specially related to conscious existence—the phonators, used in articulation, the adductors and tensors of the vocal cords. 8. Anæsthesia caused by the inhalation of ether, chloroform, &c., first abolishes the functions of conscious life; hence we should expect that, under moderately deep narcosis, stimulation of the recurrent nerve would give rise to abduction of the cords, seeing that the abductors are not affected by the anæsthetic.

More than a year ago Dr. HOOPER, of Boston, made a curious observation, the full meaning of which he did not apparently grasp. Accordingly Dr. SEMON, with the experimental assistance of Mr. VICTOR HORSLEY, has reinvestigated the matter, and the result of their work is an elaborate but lucid paper, read before the section of Therapeutics and Pharmacology at the annual meeting of the British Medical Association. Dr. HOOPER argued that,

[1] H. Krause: Experiment. Untersuchungen und Studien über Contracturen der Stimmbandmuskeln. Virchow's Archiv, vol. xcviii., 1884.

Digitized by Google

as the constrictors of the larynx were muscles whose action would be impaired by the inhalation of anæsthetics, they being essentially voluntary muscles, stimulation of the motor nerves of the larynx whilst the animal was under the influence of ether should cause dilatation of the glottis. This was actually found to be the case, provided the anæsthesia was sufficiently profound. The experiment determining this fact is remarkable and well worth further examination. A dog tracheotomised for the purpose of administration of ether, and with its recurrent laryngeal nerves exposed, is prepared for experiment. When the dog has been narcotised profoundly with ether, it is found that stimulation (with a strong current of the faradaic kind) of the motor nerve gives rise to dilatation of the glottis; if the stimulation be repeated at intervals whilst the animal is recovering from the effects of the ether, the abduction is noticed to become less and less marked, until a stage is reached in which stimulation merely causes a vibratory movement of the vocal band—a condition of neutrality, caused doubtless by a nearly equal contraction of the antagonist muscles. Continuing the experiment, the effect becomes gradually reversed, until, when the influence of the anæsthetic has practically passed off, stimulation of the nerve causes the familiar powerful constriction of the larynx. All this is very interesting; but there is another point that struck the attention of Dr. SEMON, and that was that the abduction effect of stimulation of the motor nerve was observed when, the animal being completely narcotised, the nerve had been "cut." The cause for the surprise manifested by SEMON and HORSLEY lies in this single fact—the excitation of the nerve was effected on the distal cut end of the motor nerve. Now, it has usually been asserted that the action of anæsthetics is on the central portions of the nervous system, beginning with the highest and gradually descending, consequently paralysing the functions, first, of the cerebral cortex. The recurrent laryngeal nerve is, with the exception of the branches to the crico-thyroid muscle, derived from the superior laryngeal nerve and the pharyngeal plexus, the only source of motor innervation of the larynx. 'If, therefore, in an animal very deeply narcotised abduction of the vocal cord occurs when the peripheral end of the cut recurrent laryngeal nerve supplying the muscles of that cord is stimulated, it is perfectly obvious that the effect of the narcotic is in no wise due to the central nervous system. We should be driven, therefore, to conclude that ether must act specifically either on the nerve fibres, their endings in the adductor muscles, or on the muscular substance itself, supposing that there is no peripheral ganglionic apparatus subserving the function of movement in the larynx, of which we have at present no evidence." The absolute novelty of the fact that ether has a discriminating influence on the peripheral nerves of the larynx is insisted upon by SEMON and HORSLEY — a topical influence not due to the local action of the anæsthetic on the nerves ending in the larynx, for in the majority of the experiments the ether was administered by the trachea, and must have reached the periphery of the recurrent laryngeal nerve through the circulation. The fact of histological and nutritive differences between the abductors and adductors of the larynx, above alluded to, served no doubt to pave the way for the recognition of the remarkable phenomenon of a peripheral discriminating influence of ether on the neuro-muscular apparatus of the larynx. The question naturally arises whether this influence is one confined to the muscles of the larynx, or whether it is not also likely to hold good for other peripheral neuro-muscular apparatus also. For instance, under the influence of ether, in certain degrees the knee-jerk is increased in force; this means of course that the extensor triceps contracts with greater force. Various explanations of this have been offered, and it is also worth entertaining whether the ether may not have had something of the peripheral action on the antagonistic flexor muscles of the knee-joint, thereby allowing a mechanical stimulation of the extensor muscle to have an unusually powerful effect. It should ever be remembered that the extensors and abductors of the body "die" sooner than the flexors and adductors—that is, lose their electrical excitability sooner after somatic death.

What we have already advanced will show how very complicated the physiology of the larynx has become, and we cannot but commend the authors of the paper above referred to for their freedom from dogmatic assertion, and for their ready allowance that differences in results may be brought about as the outcome of individual and generic differences in the kind of animals experimented upon. The age and accidental fallacies resulting from the influence of complications caused by damage to the nerves from prolonged exposure, as well as certain inherent difficulties of observation regarding the exact position of the vocal cords, may introduce fallacies.

ON Saturday last a discussion was raised in the House of Commons on the manner in which the duties of the medical staff of the General Post Office are discharged. It was based upon the case of an official in the telegraph department who, after an absence of a fortnight on sick leave, had attended, by order of the Post Office, to be seen by the medical officer, and who died of typhoid fever a fortnight afterwards. From the explanation given by Mr. RAIKES we are led to believe that there was no blame attachable to the acting medical officer for the course he adopted, nor was any harshness shown to the gentleman in question. But Mr. PICKERSGILL, by whom the case was brought forward, alleged that the conduct of the medical staff was oppressive to the *employés* and injurious to the public interests, and he was backed by Mr. ISAACSON, who assured the House that "a spirit of dissatisfaction existed among the people with regard to the manner in which the medical department of the Post Office was conducted." We do not know the regulations which are laid down for the guidance of the medical officers attached to the Post Office, but it appears to us that they must involve two important duties — first, that of preventing malingering, or shirking duty on pretence of sickness; and, secondly, of protecting the *employés*, when really ill, from being called upon to perform their work, or being punished for supposed neglect of it. We presume that the rule which holds in other public offices applies to the Post Office, that when a clerk is prevented from attending by illness he must forward a medical certificate. This would be a protection of the interests of the public if it were not possible to obtain such a docu-

Digitized by Google

ment on very insufficient grounds; but we know that, unfortunately, such certificates are occasionally—we trust not very often—given on inadequate data, sometimes through carelessly accepting the patient's statement of his unfitness for duty without any examination of the case, and at others from a dread of giving offence by a refusal. It is obvious that there should be some means of preventing such irregularities, and this can be done in two ways, either by ordering the attendance of the person at the office for examination by the medical staff, if he is able to go about, or having him visited at his home on forwarding an intimation of his inability to attend. It will doubtless be asserted that this is showing a distrust in the individual, and that the medical certificate should be accepted without hesitation; but we have known of instances in which a visit to the residence of the "sick man" proved that, while unable to attend his office, he was not quite so ill as to find it necessary to remain at home. We believe that a check of the nature above indicated has been found to be required by some large employers of labour, and has been attended with satisfactory results. We have no doubt, however, that this would be unpalatable in cases where the excuse is unsatisfactory, or when the inability to attend to duty is the result of personal misconduct. Mr. PICKERSGILL objected to a vote of £100 a year to pay substitutes for the medical officers when absent on leave. The duty appears at present to be fully as much as the staff can undertake, and it would be alike cruel and unjust to work the medical officers through the whole year without any period of relaxation. We would suggest therefore to Mr. RAIKES that the best way to meet such an objection would be to include an additional medical officer in next year's estimates. This would not only provide for a fair amount of leave to the staff, but would also place at his disposal an officer available for duty in case of illness of any of the others, or of the necessity arising for any special inquiry into sanitary questions connected with the service. He would also be available for visits to, and examinations of, any *employés* respecting whom the authorities might consider it necessary to obtain more detailed information.

Annotations.

"Ne quid nimis."

THE PROGRESS OF CHOLERA IN EUROPE.

DURING the week ending the 21st inst., there has been a decided diminution both in the number of places in Italy from which cholera records have been issued, and also in the amount of the mortality registered. The diminution has taken place in the north-east, in the Bay of Naples, and in the extreme south of the kingdom. In the north-east, Ravenna is the only place in which any very serious cholera mortality is now occurring, and in the Bay of Naples the disease is rapidly diminishing at Torre dell Annunziata, and it has failed to make any noteworthy progress at Castellamare. But whilst this is the case as regards Italy, the disease has exhibited further extension in Austria-Hungary. Fresh batches of cases and deaths are taking place at Trieste, Fiume, and Pola, a large number of small villages in Croatia are infected, and the appearance of the disease in Pesth has been followed by the announcement that it also exists at Raab about midway between Vienna and Pesth on the Danube. In the Trieste district there have been 576 cases and 368 deaths since the month of June, and during the same period the fatal attacks in the neighbouring provinces have exceeded 350. In the greater part of Hungary the weather is getting cold and unfavourable to the rapid diffusion of cholera; but whether cities like Pesth or the smaller towns and villages are concerned, it must be remembered that the prevailing sanitary circumstances, and especially those relating to the disposal of human excreta, are precisely such as are usually associated with the wide prevalence of cholera. On the 17th inst., there had been 53 cases and 11 deaths at Raab, and between the 12th and 18th inst. there have been 61 cases and 19 deaths in Pesth. The latest news is to the effect that 33 cases and 4 deaths have also occurred in Austria proper.

J. SAMPSON GAMGEE.

THE intimation of the death of Sampson Gamgee, is one of the most unwelcome pieces of news which we have received for some time. The accident which he had met with and his latent renal infirmity were known to us, but he was reported to be doing well, and his letters were in his most vigorous style, when lo! the intelligence comes of his decease. He was a rare man. That he had faults we may concede to those who love truisms. But what virtues he had, what grace of speech, what kindness of heart, what cultivation of mind. How complete were the principles of his surgical art—original yet conservative. How he loved the working men of Birmingham, and urged them to love its hospitals and to help them; and yet how keen was his sympathy with intellect in its purest forms. How he reverenced all that was classical and traditional in the profession, and yet what sympathy he had with its rank and file and the men who bear the burden and heat of the day. His own day was, we fear, not without heat and burden, and for years past he has had the look of impaired health, but he was always ready to lend a helping hand or speak a gracious word; and as a practical surgeon he has left in his book on the Treatment of Fractures and Wounds a legacy which will mark and foster the fame of surgery as a tender and conservative art. We cannot forget his old connexion with this journal, and his faithfulness to it even to the last. He was one of the few writers who had served both the founder of this journal and the son whose loss we now deplore. We can ill spare such men, and his loss happens unfortunately just now, when the profession needs men whose love of the past does not blind them to the needs of the present.

PROPHYLAXIS OF PHTHISIS.

AT the recent meeting of the British Association, Mr. G. W. Hambleton read a paper entitled "The Scientific Prevention of Consumption," based upon his views—to which we have lately alluded—as to the etiology of the disease, which are embraced in the sentence, "Those conditions that reduce the breathing surface of the lungs below a certain point in proportion to the rest of the body." The conditions in question are, as may be expected, very numerous, comprising sedentary occupations, overcrowding, want of exercise, defective seats, clothing, &c., leading to habitual disease of the lungs or the undue compression of the chest. In fact, consumption is, on Mr. Hambleton's doctrine, invariably "acquired." Its prophylaxis, then, requires a free country life, well-ventilated rooms, suitable chairs, and clothing free from constriction and not too heavy. The physical training, commenced in the nursery, should aim at the full development of the thorax, and all out-door occupations and amusements should be encouraged in youth to this end.

Unless the breathing capacity, as shown by measurement, is up to the normal, the individual should not engage in any trade or occupation such as would compress the chest or injure the lungs by inhalation of dust; whilst those who have to follow such pursuits should by exercise of the lungs endeavour to counteract their evil effects. All of which advice, without being novel, is sound and forcible; whilst if it could be followed as widely as Dr. Hambleton would wish, it would doubtless do even more for the public health than reduce the mortality from consumption.

COMPULSORY ATTENTION TO CHILDREN'S TEETH.

THE prevalence of caries of the teeth amongst so large a majority of the units that comprise civilised communities, and the consequent pain and inconvenience entailed, and, perhaps unconsciously, the absence of those pleasures attending a good digestion which makes up so large a part of individual happiness, have induced the public to interest itself in the pathology and treatment, especially prophylactic, of these organs. Now, if we wish to get at the root of the evil we must commence our treatment with the deciduous teeth. Many patients—nay, even medical practitioners—ask, what is the use of preserving teeth which have only to serve their purpose for a time and which nature will replace? If a surgeon were asked what is the use of provisional callus in a case of fracture his answer would be readily formulated, and just such an answer is applicable to the teeth. We will run over just a few of the points that may result from disease and its neglect. First, with regard to the child's health. With decayed teeth, and often, in addition, chronic gumboils, the little sufferer is kept awake at night and his digestion affected by inability to masticate his food, and more so by swallowing the fetid discharge from the abscesses. As a consequence the child becomes weak and puny, and so the already developing permanent teeth suffer from the constitutional disturbance. Supposing each tooth as it becomes the seat of pain is extracted, then the masticatory power is greatly enfeebled, and, moreover, it has been shown that where many deciduous teeth have been removed, especially in the case of the canines, the jaw does not develop as rapidly as it should do, and consequently, when the permanent teeth erupt, some take their position inside and some outside the arch, which irregularity is a potent predisposing cause of caries, apart from its unsightliness. Again, take for instance a very common case, that of a second temporary molar extensively decayed. The first permanent molar assumes its due position posterior, and the first bicuspid anterior, to it. Both these permanent teeth are frequently found affected on the side corresponding with the deciduous tooth, and the disease is undoubtedly due to the infection from decomposing food harboured by it. Although much more might be said upon this subject, we think that enough has been advanced to show the importance of first teeth with reference to the welfare of their successors, which should, but so often do not, do duty for a lifetime. We believe that nothing short of the periodical examination every six months, and treatment if necessary, of the teeth of children can effectually cope with this evil. At the recent meeting of the British Dental Association, Mr. Fisher, of Dundee, read a very able paper, in which he strongly advocated that dental surgeons should be appointed, with sufficient salaries to ensure the possibility of conservative treatment, and not, as heretofore, only extraction, to all public schools, reformatories, industrial and endowed schools, training-ships, &c. He has examined the teeth of a large number of children attending schools, and found that on an average over 75 per cent. required dental treatment; he also mentions the startling fact that the principal manufacturers in London supply 10,000,000 artificial teeth per annum, showing the enormous loss of natural teeth amongst the community. There is already a move in the direction of Mr. Fisher's suggestion; as we noticed some time ago, the North Surrey District Schools have appointed a dental surgeon at £60 per annum, and since then the District School of Upper Norwood has a dental officer. The Metropolitan and City Police Orphanage has had for some years a dental surgeon.

"THE FALL OF THE LEAF."

THE slight frosts which have occurred an hour or two before dawn in the past fortnight have already had their effect on our trees, changing the varied green to the exquisite and variable red and russet tints of autumn. This will soon be followed by the "fall of the leaf." Many an exquisite shady spot in summer will now become damp and chilling, and a musty odour of decaying vegetation will take the place of the fresh and invigorating shade of summer. Sensitive natures are very susceptible to this alteration, and feel that health necessitates a change of abode during the later autumnal months. Nor is the deleterious influence of decaying vegetation confined to sensitive natures alone. Stronger natures are alive to the influence of the "falling leaf." The ground becomes bestrewed with vegetable decay, and the atmosphere impregnated with the products of decomposition. The air becomes musty, and lowly forms of vegetable and animal life are about. The fungus takes the place of the sweet-scented herb, and damp moss that of the green sward. The honey-fed bee keeps nearer the hive, and is replaced in the garden and shrubbery by the gnat, the midge, and carrion-fly. Modern science teaches that all active organic decomposition and autumnal vegetable changes are inimical to higher animal life. Even insects are not free from this risk; they pass into a state of torpidity in autumn, and "should any particular moisture accidentally accumulate on them, it affords a seed plot for certain minute fungi to come up and grow in." So wrote Kirby and Spence more than fifty years ago. What is true of insect life has been proved to be equally true of higher forms of animals and man, with only such modifications as their different natures imply.

"THE PROTEAN MAN."

SOME wonder is being excited in the provinces of France by the exhibition of an individual who dubs himself "L'Homme-Protée." The number of shapes and attitudes that the man is able to assume is said to be so great that the title of "Protean" may well be allowed if the individual manifests only half the powers attributed to him. Now, whatever he can do, it is obvious that his faculties are the same in kind as those possessed by the rest of mankind, though the degree in which the faculties are developed may vary vastly; so that we cannot agree with the writer who asserts that the contortionist transforms himself, thanks to his *peculiar* system of muscles. Doubtless his frame is wonderfully mobile, and every part of his nerve and muscle apparatus has been trained to the utmost. It is possible, also, that M. Aiguier is gifted with the power of influencing the action of muscles over which man usually exercises no voluntary control, though with practice many may acquire the capacity if they set themselves about the task in the proper fashion. The Protean man, it is said, can assume the rigidity of a statue, so that, the body sharply struck, the blows fall as on a block of stone. This probably means that the man has the capacity to develop

Digitized by Google

at will the cataleptic condition. By varying the activity of different muscles of the abdomen he is alleged to be able to give his trunk a great variety of shapes and sizes, from that of the proverbial alderman to that of the lean and haggard student. He is even accredited with the possession of the power to appear as lean as a skeleton; but this must surely require an effort of the imagination, as well as a still greater effort on the part of the muscular and vascular apparatus of the contortionist. What most astonished M. de Quatrefages, who examined him, was the ability to stop the flow of blood, now on the left, now on the right side of the body; this was ascribed to the influence of unilateral muscular contraction.

HOSPITALS AND MEDICAL EDUCATION.

A PAMPHLET entitled "The Relation of Hospitals to Medical Education," by Dr. C. F. Withington, of Boston, will interest many on account of the care and judgment with which it treats an important subject, which is not quite a simple one. In the first part of the paper the duty of hospital governors to make use of their unrivalled opportunities of instruction is insisted on. It is the proper part of such institutions, as the author sensibly observes, not only to aim at the cure of patients within their walls at a given time, but, moreover, to gather from observation of all such, and to share with others, experience which will work for the health of many in time to come. The personal rights of patients are considered at length. As regards this point—a delicate one in some cases—a good deal of tact and fellow-feeling blended with perception of practical necessity appears in the advocacy of carefully conducted clinical and pathological investigations. There is much truth in the author's contention that resident posts as well as higher hospital appointments ought to be assigned on the ground of merit alone. We cannot quite agree with him, however, that competitive examinations are to be regarded as a good test of merit in such cases. A plea for the training of male nurses, and for the diffusion of some knowledge of nursing among the public generally, is noteworthy. Another suggestion in this paper is that workshops for the construction of surgical apparatus might be established within the hospitals. Surgeons would then supervise the making of their own appliances, and students might arrive at some practical acquaintance with mechanics as applied in surgery.

ANOTHER FORK IN THE STOMACH.

M. POLAILLON reported, at a recent session of the Paris Academy of Medicine, an interesting case, which was then under his care, but which terminated fatally, of a man who had swallowed a table-fork. The patient explained very exactly, as was afterwards found, the position of the fork, its handle being in the right hypochondrium, and the prongs directed obliquely upwards, backwards, and to the left. Scarcely anything, however, could be felt by external palpation, although the man was of spare habit, and M. Polaillon at first had some doubts as to the existence of the foreign body, especially as an œsophageal sound gave no indication of anything hard when passed into the stomach. An instrument was then constructed on the principle of the galvanic bullet-probe, and a slight indication was obtained with it. A delicate magnetic needle was, however, distinctly affected when the man's epigastrium was brought near it; and a powerful electro-magnet, placed a few millimetres from the abdominal wall, produced, on closing the circuit, an arching of the skin, as if a body within the abdomen were being attracted towards the poles. A suspended electro-magnet also oscillated towards the abdomen whenever the current was passed through it. There being, therefore, no longer any doubt as to the existence of the fork in the stomach, M. Polaillon made an incision, commencing at the ninth left rib, one centimetre within the border of the costal cartilages, and carrying it for seven centimetres in the direction of the xiphoid cartilage, as recommended by M. Léon Labbé, as the best position for reaching the stomach with certainty. In this case the stomach wall, which was very thick, was seized without difficulty, temporarily secured and opened, the fork easily removed, and the gastric wound accurately sutured with catgut and then returned. The abdominal wound was afterwards brought together with silver sutures and dressed antiseptically. The operator remarked that he had departed from the method hitherto employed of causing the stomach to adhere permanently to the abdominal wall and setting up a fistula; the result would show whether his plan succeeded as well as the *suture perdue* does in intestinal wounds. A discussion took place subsequently on the possibility of succeeding by means of an electro-magnet in extracting a fork from the stomach through the œsophagus. This M. Leroy de Méricourt thought could never be done because of the small size of the cardia; but MM. Polaillon and Goubaux suggested that sufficient dilatation might, perhaps, be caused by the induction of vomiting.

CHRIST'S HOSPITAL.

THE parents of boys at the Hertford Branch of Christ's Hospital have been informed that pupils may return to the school. The summer holidays have been extended, owing to an epidemic of sore-throat at Hertford; but this has now subsided, and the continued absence of the boys is no longer necessary. Dr. George Turner, the medical officer of health of Hertford, reported on Sept. 9th to the local sanitary authority that "the disease was generally of a very slight nature, and under ordinary circumstances would not have given rise to any alarm, but taking into consideration the very general prevalence of throat disease in the country, an importance which perhaps the gravity of the majority of the cases would not suggest has been attached to them. No notices of outbreaks of zymotic diseases have been received by me for some time, and, generally speaking, the town is in its usual healthy condition." The school authorities have undoubtedly acted wisely in awaiting the termination of this prevalence of throat disease before reopening the school, and the desire they have shown to guard their charges from ill-health should deserve the thanks of the boys' parents.

ACCIDENTS TO SLEEP-WALKERS.

IT seems strange, on the first blush of the matter, that so very few accidents befall sleep-walkers. The proportion of instances in which any injury is sustained by the subjects of this remarkable state of semi-sleep is very small. The explanation of the immunity is doubtless to be found in the fact that it *is* a state of semi-sleep in which the sleep-walker makes his excursion. He is sleeping only so far as *part* of his cerebrum is concerned. The rest of his brain is awake, and therefore it is really not a strange feat to walk carefully and escape injury, doing all the necessary acts of avoidance while carrying out some dream purpose, just as a walking purpose is fulfilled. This hypothesis obviously requires a very full explanation of such an accident as that by which a sleep-walker recently came by her death—namely, falling out of an open window. It is not likely to have been part of the dream to get out of a window. There must have been some error in the carrying out of the process; such, for example, as turning to the right instead of the left on leaving a room, and thus walking through a low window instead of through a doorway. As a rule the senses are sufficiently on the

Digitized by Google

alert to enable the sleep-walker to take all precautions for safety, and when he comes face to face with a difficulty involving more than automatic or subconscious self-control, he wakes. We should like to know more of the case which has just ended fatally from some competent medical observer who has studied the development of this interesting disorder in this particular instance. Surely a practitioner was consulted. No case of sleep-walking should ever be left without medical scrutiny and counsel. In sleep-walking there is the making of madness, and in its inception this disorderly sleeplessness ought to be stayed.

"CLERGYMAN'S SORE-THROAT."

IT may not be generally known that both at Oxford and Cambridge facilities are afforded to young men about to enter the Church or any other profession in which the voice may be subjected to over-exertion, to undergo a systematic course of instruction in the "management of the voice." In his earnestness to be impressive, it is very common to see a clergyman bend forward in the pulpit, protruding the body and still more the head from the proper vertical line, and in this way subjecting his voice to a much greater strain than is necessary. The huskiness which ensues often lessens the impressiveness of his discourse, and he himself becomes exhausted in the effort. The course of instruction now afforded at the Universities enables a clergyman to manage his voice so as to make the most of his vocal powers and diminish the risk of lessened tone. With the shoulders well in position and the chest expanded thereby, the head being kept upright and the under chin in a horizontal line, it is surprising how much more distinct the voice becomes, and how much further it is carried. A course of instruction in the management of the voice would do much to lessen the inconvenience of clergyman's sore-throat, and to those not yet suffering it might prove a valuable preventive. One of our present bishops, when at Oxford, encouraged the large number of young men under his following to undergo a course of vocal gymnastics. Numbers of clergymen, and some of our own profession engaged in teaching, have benefited by such a course.

"MAN-CULTURE."

THIS was the expressive and apposite term which Sir George Campbell, in his opening address to the Anthropological Section of the British Association, commended for general use in the same category as oyster culture, bee culture, and the like. The term is a good one, and it will be well if its adoption should bring the idea embodied in such high-flown phrases as "elevation of the race," "civilisation," and "education" in its broadest sense, down from the region of sentiment and emotional enterprise to the plain matter-of-fact business of daily life and policy. In truth, man-culture is a practical duty imposed by Nature on humanity, and in respect to which every one of us has a share of responsibility commensurate with the intelligence he may possess, or to which he lays claim. It is impossible for a sane and rational being to avoid the consequences of neglect in reference to this duty. They must come down on the individual or upon those to whom he stands in the relation of a trustee or progenitor. Parents towards their children, and every member of the *genus homo* towards those with whom they are brought into contact—whether mentally, physically, socially, or in whatsoever other way influence may be exerted or withheld for the good of others—are benefactors or malefactors in respect to their kind. Fetish and the idea of destiny are unquestionably inimical to the fullest development of this idea, because it begins with the propagation of life in the species, and dominates the whole of existence. Precisely as the animals below man are cultivated by foresight in reference to breed and nurture by food, exercise, and surroundings, so must man, and thus most assuredly will he, sooner or later, be cultured. The science of anthropology is the master science; and yet, while its scope is of the widest and its subject thought as far-reaching as the duration of man himself, it is necessarily a mere episode in the history of knowledge. "All about man" can never, in the nature of things, be even seen, much less can it be studied, from a single standpoint. All the sciences are tributary to the knowledge of self by humanity, and yet no man, or class or school of men, can do more than take a cursory view of the whole while essaying the special study of some one branch of knowledge in particular. Nevertheless, it is well there should be for the nonce a so-called "science of anthropology," and it will serve a useful purpose just so far as it is perceived to be only a cursory general view of what must be examined more closely in detail. If the anthropologist, as such, should make the mistake of supposing that he can ever come to close quarters, so to say, with his manifold subject, he will inevitably become mischievous, instead of being useful. Anthropology, properly estimated, is the logic of natural science; but it is not, and never can be, natural science itself. The Anthropological Society has missed its aim and impaired its usefulness by forgetfulness of the fact that in respect to no single branch of the science of man can it be more than amateurist and *dilettante*. There is reason to fear that the new branch of the British Association may fall into the same error. The only policy that can rescue it from this untoward end is that which we hope we are right in recognising as the idea running through Sir George Campbell's address—namely, that anthropology, to be useful, must take the practical and applied form of man-culture; and the instant this endeavour to realise the ideal is commenced, *anthropology*, in its scholastic conception, will be found to have fallen to pieces—an exploded idea.

CHOLERA RESEARCH.

Dr. E. O. SHAKESPEARE, who was sent by the United States Government to India with a view to investigate cholera, has returned home, and the publication of his report may be shortly expected. He is stated to have arrived at conclusions confirmatory of those of the German Cholera Commission, and therefore different from those arrived at by the English Commission. We recently drew attention to the fact that Dr. D. D. Cunningham's (a member of the English Commission) later investigations had also led him to materially modify his previous conclusions respecting the pathogenic importance of the comma bacillus.

SAFETY LAMPS IN MINES.

THE public will be pleased to notice that the lighting of mines has become of late a somewhat prominent question. This is doubtless the result of the investigation conducted by the Royal Commission. Among other conclusions arrived at by that body, the fact that safety lamps rather than naked lights should be used in all workings which were dusty or liable to invasion by gas was particularly emphasised. Fire-damp, it was shown, is not the only source of explosions. A quantity of this gas, quite insufficient in itself to account for such an accident, if brought in contact with a cloud of fine coal-dust, may easily, on the ignition of the latter, lead to a disaster. Another point brought out was, that one result of ventilation had been to cause through currents of considerable velocity in the air of mines. Consequently, when impure air thus driven along is brought in contact with the unprotected lights, or even with some forms of lamp, an explosion is not unlikely to occur. These

Digitized by Google

statements will sufficiently explain why in one mine the use of naked lights has been condemned in spite of established custom; while in other instances an effort has been made to induce proprietors to use, instead of the older kinds of lamp, a modern and improved form which is more capable of resisting currents of high velocity.

METROPOLITAN WATER COMPANIES.

MR. F. M. CORNER, medical officer of health of Poplar, has made in his annual report a pointed reference to the evils which result from the action of the metropolitan water companies in cutting off the water-supply from tenement houses on account of neglect of payment of the landlord, depriving the inmates, who are themselves innocent of any negligence, of one of the first necessaries of life. He gives a graphic description of the effect of this conduct, the choking of drains, the opening up of ground and drains, the removal of filth accumulation, and all the injury to health which follows. Specific instances are quoted where numbers of houses, each occupied by several families, were deprived of their water-supply, some for twenty-six days, others for seventeen, while a third group, which had a population of seventy-four persons, were without water for a space of fourteen days. Mr. Corner has done well in giving publicity to these facts; they cannot be too strongly brought before the public. It is a matter for profound regret that the hope of legislation last year ended in disappointment. No one wishes water companies to lose the returns which are due to them, but there will be no difficulty in giving them all the necessary powers for the protection of their own interest without resorting to a method which produces the scandalous conditions of which Mr. Corner gives account. The reply of Lord Randolph Churchill, for the President of the Local Government Board, on Monday, to a question in the House of Commons relating to metropolitan water-supply has given rise to the expectation that London will be soon protected against the water companies, who appear to put their own interest altogether before the public welfare.

INQUESTS WITHOUT NECROPSIES.

AN inquest was recently held by Mr. William Carter, coroner for North-East Surrey, at the Windmill Tavern, High-street, Lambeth, touching the death of Mr. Everard Woods, L.K.Q.C.P.I., aged twenty-six. From the evidence it transpired that deceased was assistant to a medical man in Whitechapel, and that by reason of ill-health he had quite recently resigned his situation for the purpose of taking a trip to New Zealand. He was in easy circumstances, and more than one witness deposed that there was nothing in his habits or demeanour to suggest the likelihood of his committing suicide; in fact, there was absence of any known motive to such an act. The facts, as related to the jury, seem to us far more consistent with the theory of murder. Mr. Woods, on the evening of his death, had visited a friend, and had expressed himself as feeling better. A short time after this two strange men accosted a waterman, who was standing on the Lambeth Pier, and asked if he had a boat, adding that a man had jumped from the Albert Embankment. Having given this information they disappeared, and nothing further was seen of them. They neither offered to assist the waterman to recover the body nor gave notice to the police of the tragic occurrence. On the body of deceased some silver and copper coins were found, but his gold watch and pocket-case were missing. It is not probable that he had pledged them, for he had left seven or eight sovereigns at his lodgings. No medical evidence was taken at the inquest, and, if report is true, the coroner took the statement of his officer as to the absence of bruises. The jury returned an open verdict of "Found drowned." If ever there was a case where it was important to ascertain the exact cause of death it was this. From a scientific—that is a reliable—standpoint, there was nothing tendered in evidence to show that death was not occasioned by violence, and the corpse thrown into the water. The mere *ipse dixit* of a coroner's officer on a subject requiring skilled expert inquiry is worse than worthless. It serves to beguile a jury, and it seems to satisfy the judicial mind of a coroner, but it fails to help the investigation as to when, where, and by what means a certain person came by his death. The mysteries of the Thames are not likely to diminish in number so long as they are intentionally left as "open questions." We maintain that it is the function and the duty of a coroner's court to leave no stone unturned in order to satisfy the public mind and the demands of justice, in the question of the equivocal nature of a person's death. It is high time the attention of the Home Secretary was directed to the fact that many inquests are frequently of worse than negative value.

A CORFIOTE LAZZARETTO.

SANITARY prejudice dies hard. Quarantine, in spite of wounds that ought to have been mortal, survives in full force along the Mediterranean seaboard, and, if it ever receive the *coup de grâce*, it will be from the conviction that as a preventive it is worse than the disease. Opinion, in this sense, is rapidly developing, and even finding voice. A correspondent writes from Corfu: "For five days I have been in the lazzaretto here, and I feel it my duty to send you a line for the benefit of such persons as may be contemplating a voyage to Greece. The eleven days required by the regulation to be spent here will be found far worse than in any prison. Not only is the building itself in a dangerously tumble-down condition, but the rain, the rats, the lizards, and every variety of insect have the run of the rooms, while the food is bad and the cooking worse. In the lazzaretto we have no physician. Once a day it is whispered that the doctor has been and has returned to Corfu; but few see him, and I am among the majority who find him conspicuous by his absence. One official only, the director, M. Milziade Capozzari, is courtesy itself; but pleasant manners and soothing words do nothing to make this lazzaretto life endurable, where every requisite for comfort and even health is wanting." Similar testimony as to the horrors of Mediterranean lazzarettos has already come from Italy and Spain.

THE UTILISATION OF TOWN REFUSE.

A CORRESPONDENT, writing in *The Times* of Tuesday last, comments on the difficulties with which Londoners have to contend on account of the want of system in cleansing London streets and removal of house refuse. He gives a detailed account of the Glasgow method, by which house ashes are placed upon the street in buckets, pails, boxes, or other receptacles, between the hours of 8 P.M. and 9 A.M. The whole of this matter is removed every night, and in case of the houseowner having omitted to give the dustman this opportunity, a second collection is made in the morning. Men accompanying the cart are instructed to sweep up any dust that is spilt, and during the night the streets are carefully swept, and the refuse removed in the morning round. This refuse, he states, is then deposited without the town, whence it is subsequently removed for manuring the land. It has, indeed, sufficient monetary value to warrant farmers purchasing it at rates which not only pay the cost of carriage, but make a considerable return for the cost of collection. It is a question whether the agricultural districts surrounding London would be sufficient in extent

Digitized by Google

to utilise the immense quantity of refuse which the metropolis daily produces; probably some means would have to be provided by which its destruction can be effected, especially at those seasons of the year when farmers would have no need for it. The longer distances it would have to be carried would add largely to the expense, and probably the adoption of the Glasgow method would not solve the problem in a financial sense. Nevertheless, the gain to London health of a daily collection of house dust would warrant a considerable sacrifice if this could be ensured; but it is too much to hope it will be seriously attempted until some reconstruction of sanitary administration has placed the metropolis upon a level with other towns.

THE WATER-SUPPLY TO EAST LONDON.

THE East London Waterworks Company are certainly unfortunate. Past events have not won for them any great reputation for carefulness, and now we learn that the local board of West Ham are engaged in trying to trace the cause of several severe cases of illness in the district which are stated to have been caused by tainted water. Dead eels, it appears, have been found in the pipes in High-street, Carpenter's-road, and other districts of Canning Town, and thus the inhabitants must have been drinking water tainted with putrid matter from these decaying animals. It is important to learn how, with any proper filtration worth the name, eels can pass into the supply-pipes to houses. Doubtless this will be inquired into by the directors of the company, but the conclusion is certainly suggested that sufficient care is not taken to protect drinking water from impurities. If eels can thus make their appearance in the mains, there is too much reason for fearing that matter of smaller size, but more injurious in its effects upon health, can follow the same course; and it will be interesting to note what account is given by the official examiner of the analysis of the water of this company during this period.

THE SANITARY STATE OF BATLEY.

THIS Yorkshire cloth-manufacturing town has been visited by Dr. Barry in connexion with the general survey which the Local Government have inaugurated as regards places that were suspected of containing conditions favourable to the development and spread of imported cholera. Although an excellent water-service is available, this district has progressed but little in other matters; and it is especially noteworthy that although the authority's attention has for some ten years past been prominently called to the evils connected with their neglected system of midden-privies, those structures are still found in a state which must be a cause of grave nuisance and risk to health. Dr. Barry's strong comments on the subject met with a reception that gives some hope that the subject will soon be energetically dealt with.

CHEAP MORTAR.

MUCH attention has recently been devoted to the materials used in the construction of dwelling-houses, but it will be a new fact to many that mortar is made from sediment taken from London sewers. The bye-laws of the Metropolitan Board of Works do not distinctly specify the materials of which mortar shall consist; hence it is no easy matter for district surveyors to control, even if they desire to do so, the actions of builders in this respect. The Bermondsey vestry were informed at the last meeting that certain houses in the course of construction in Long-lane were being built with mortar composed of sediment taken from the sewers and which, curiously enough, had been sold to the builder by the contractor of the Metropolitan Board of Works. The sewer deposit is washed by firms who carry on a trade by extracting from it valuable products. Probably much difficulty will be encountered in preventing the use of this material, and doubtless good will result if the Metropolitan Board are compelled to alter their bye-law for this purpose. The excellent mortar which the Manchester corporation obtain from the destruction of house refuse is sufficient proof that London could provide herself with equally good material if she would adopt the same system of destruction and assist at the same time in the solution of the vexed question of the disposal of this matter. Corporation mortar in Manchester and other towns has, to a large extent, superseded that obtained from other sources.

THE MELBOURNE HOSPITAL.

IT is high time that the authorities at Melbourne took steps to supply the city with a new hospital. The latest advices inform us that the present building, always unsuitable, has become so unhealthy that cases of erysipelas and pyæmia are alarmingly frequent; and that, in spite of the full adoption of antiseptic surgery, one of the surgeons (Mr. Fitzgerald) has declined, except in cases of urgent need, to operate any more in this building, and lately sent a patient back to Sydney rather than allow him to risk his life by submitting to an operation in Melbourne. It would seem that the erection of a new hospital is delayed mainly in consequence of the difficulties attending the selection of a site. The University Council refuse to have one erected—where, indeed, one would think it would be most advantageous—in the vicinity of the medical school of the University. But such a refusal is of a piece with the action reported by us last week, and seems to show that the Melbourne University authorities hardly comprehend the importance of a good clinical education. But whether on University ground or not, a site must be speedily found. It is a reproach to a city of upwards of 300,000 inhabitants, which boasts of the magnificence of its public buildings, that it should be provided with a hospital in which a surgeon dare not operate lest his patient should die of blood-poisoning.

"HIGH" FOOD.

THERE are "high" and "high" in the matter of the ripeness or fitness of flesh foods. We are not disposed to follow the speculative theorists who hypothecate ptomaines and "bacilli of living germs"—whatever that phrase may mean—as the effective causes of gastric and general irritation following the eating of "high game or old cheese." These speculations may be justifiable, but it is easier to suppose that something very similar to the disturbing effect of ferments or fermenting material in the case of new or *sick* wines may be produced by meat which is undergoing special varieties of decomposition. It is certain, as a matter of observation, that sometimes—under conditions not easily defined—the flesh of game will "go wrong" in the process of becoming "high"; and, without presenting any special characteristic discoverable by the aid of the microscope, irritate the stomach and produce even formidable disturbances. It would appear that the occurrence of this error in the maturing process is rather due to the influence of particular states of the atmosphere acting upon the tissues undergoing metamorphic processes, and more closely related to the condition of hydration than to that of oxygenation. We do not sufficiently appreciate the part which hydration, or dehydration, plays in the chemico-vital processes of tissue change. Water is a more important agent than simple oxygen in the changes which take place in organised matter, whether living or dead, as it is the more important factor in metabolism generally.

THE FRENCH ACADEMY OF MEDICINE PRIZES FOR 1887.

THE arrangements for the prizes offered by the French Academy of Medicine for competition during 1887 are as follows:—The Academy Prize (1000 francs): "Vaginal Hysterectomy, the Indications and Operative Procedures." The Argenteuil Prize (10,000 francs; this prize, which is sexennial, will be awarded to the author of the most notable improvement in measures for the cure of urethral strictures or to the author of the best work on the treatment of other diseases of the urinary passages. The Barbier Prize (2000 francs) will be given to the discoverer of the most efficient means of curing diseases considered incurable, such as rabies, cancer, cholera, &c. "Encouragements" may be accorded to those who come nearest to attaining the object without actually accomplishing it. The Henri Buignet Prize (1500 francs) is for the best written or printed work on the applications of physics or chemistry to medicine. Foreigners are not allowed to compete for this prize. The Capuron Prize (1000 francs): "Post-partum Involution, the Changes and Pathological States which result." The Civrieux Prize (1000 francs): "Vesical Neuralgias." The Daudet Prize (1000 francs): "Actinomycocis." Authors must present original observations made in France. The Desportes Prize (1200 francs), for the best work on Practical Medical Therapeutics. The Ernest Godard Prize (1000 francs), for the best work on External Pathology. The Hygiene of Infancy Prize (1000 francs): "A Clinical Study of Athrepsia." The Laval Prize (1000 francs), for the most meritorious medical student. The Lefèvre Prize (2000 francs): "On Melancholia." The Auguste Monbinne Prize (1500 francs) is a fund to be expended for scientific missions, &c. The Portal Prize (600 francs): "On Primary Renal Tuberculosis." The Saint-Lager Prize (1500 francs), for experiments to produce goitre in animals by administering substances extracted from the water or earth of goitrous regions. The prize will not be awarded unless the experiments have been successfully repeated by the Academy's commission. The Vernois Prize (800 francs), for the best work on hygiene. Competing essays for all these prizes must be sent to the Academy before May 1st, 1887, written in French or Latin, accompanied by a sealed envelope and a device to identify the author. The condition of concealment of the author's name does not apply to competitors for the Argenteuil, Barbier, Buignet, Desportes, Godard, Monbinne, and Vernois prizes.

NEW MEASURES AFFECTING HOUSE-BOATS.

THE campaign we opened against the pollution of the Thames by house-boats and steam launches has already led to a practical result. A bye-law has been drawn up empowering the exaction of a penalty for defiling the Thames, and is only waiting to receive the approval of Her Majesty in Council. Armed with this new enactment the Thames Conservators will be able to prevent the draining of house-boats or launches directly into the water. This is a decided step forward, but it does not suffice to make a new regulation; proper means for its enforcement must at once be organised. Every existing house-boat or launch should be inspected, and structural alterations made which will prevent the draining into the Thames. Then, again, on special occasions, such as the Henley Regatta, a scavenger boat should be provided. On the other hand, as all these new services will occasion some cost and may involve an increase in the number of persons in the employ of the authorities concerned, we cannot agree with Lord Randolph Churchill in considering it inexpedient to impose a special tax on these boats. There are taxes for men-servants, for armorial bearings, &c. &c. Such taxes commend themselves to the general approbation, as only touching those who can well afford to pay. A house-boat is equally an object of luxury, and if these pleasure contrivances involve extra outlay on the part of the community, it is only fair they should bear this expense. Feeling that good sanitation must necessitate some financial sacrifice, it is in the name of sanitation we regret extra means have not been found to defray the cost of extra work. Nevertheless, it is satisfactory to note that our protests have been well received, and are likely to bring about, and without further delay, at least a partial amelioration.

A SPANIARD ON THE BRIGHTON MEETING.

IN some letters to the leading Spanish medical journal, *El Siglo Médico*, Dr. S. Buisen gives an account of the gathering of the British Medical Association at Brighton, more from the social than from the scientific point of view. He compares the Dome to the theatre in the Alhambra, though, as he says, the former is much the larger. The Pavilion also pleased him, though, like other people, he could not help criticising its extraordinary style or styles of architecture. However, both buildings were splendid (*grandiosos*), but "it is well known how the English do these things." The excursions and the hospitality, too, were not thrown away on our Spanish *confrère*, who appears thoroughly to have enjoyed himself. What seems to have struck him especially was that such a gathering of from 450 to 500 medical men should have been assembled, arranged for, and entertained, many of them with their families, without any hitch having occurred. He is quite aware that such bodies as the British Medical Association are not formed in a day, and that, much as he would like to see such an assembly of his brethren in "dear old Spain," it can hardly be expected on such a scale for a good many years to come. There can be no reason, however, why scientific practitioners in Spain—of whom, by the way, there is a greater number than most people are aware of—should not from the starting-point of some of the existing societies form a similar association.

THE POPE'S MODEL CHOLERA HOSPITAL IN ROME.

A CORRESPONDENT of the *Globe* gives an interesting account of the "model cholera hospital" which the Pope has caused to be erected in Rome for the accommodation of cholera patients in case of an epidemic. Contact with the outer world is carefully guarded against by grated windows, telephones, and by a revolving barrel with half its circumference open, by which provisions are taken into the hospital. The water-supply is drawn from a well, and is quite separate from the city supply. The drain is formed of an iron tube sixteen inches in diameter, the joints being hermetically sealed with lead. There is a disinfecting boiler in which corrosive sublimate is placed. There is a room called the "chamber of observation," which has a staircase leading up to the first floor. In this room dead bodies are placed for a given time, as it is well known that cholera patients often show signs of being quite dead when really only apparently so. The room is, by means of an electric apparatus, in communication with the director's office. The body being laid on a bed, both hands are put into a sort of copper muff; between the hands is put an instrument so sensitive that, should there be the slightest movement of the hands or any other part of the body, this instrument would instantly close the electric circuit, and the bell in the director's office would be set ringing; at the same moment another instrument registers the number corresponding to the bed upon which the body is lying. The chamber is warmed by steam so as to facilitate resuscitation. The laboratory is provided with a gasometer for the storage of oxygen, which is taken to

Digitized by Google

the wards for administration in gas bags. On the ground floor are four wards for doubtful cases; should they get worse they are sent up in the lift to the cholera wards above, their clothes and bed-linen being immediately burned. Another room is set apart for women in childbirth, and there are two more for undressing patients, so that the infected clothes may be destroyed, the Pope furnishing new clothing for all recovered cases. The cubic space allowed for each bed is thirty-six cubic metres. The ventilation is carried on by means of funnels with gas jets below. The chapel is in communication with the sacristy of St. Peter's, so as to form an easy access for the Pope should he wish to visit the hospital; but before returning into the sacristy his Holiness and suite would have to go into a room near it for disinfection. In the event of there being more cases than the hospital can hold, provision has been made for building large sheds in the garden. This hospital was begun in October, 1884, and finished in April, 1885. When the cholera was raging with such violence in Naples, Leo XIII. determined upon making preparations should the scourge visit Rome. It has never been necessary to use it, but it is always ready in the event of an outbreak, and should prove of much use in extirpating it.

THE DOCTOR'S FEE IN CASES OF SUICIDE.

THE case of a would-be suicide refusing to pay the doctor who has saved his life, which was mentioned in our "Northern Counties Notes" of last week, is matched by an incident which occurred in Berlin, and which is just now going the round of the German medical journals, concerning a man who went into a beershop and poisoned himself there. The landlord despatched his daughter for a doctor, who did what he could for the man and sent him to the hospital. When he recovered he refused to pay the doctor on the ground that he had not desired his services. The police, too, declined to settle the account, as also did the landlord, though it amounted only to the modest sum of four shillings. The Berlin Medical Defence Society then took the matter up and sued the landlord, who, in turn, was defended by the Publicans' Society, and though the matter has now been in litigation for more than four years, the doctor, instead of getting his four shillings, has had to pay the costs, which to us, considering the circumstances, appear little enough, being only £2 7*s.* 3*d.*, yet nevertheless too much good money to throw after bad.

STATISTICS OF CEREBRAL TUMOURS.

AN instructive piece of statistical work has been contributed to the current number of Guy's Hospital Reports by Dr. Hale White, on the cause, operative treatment, mode of death, and general symptoms of 100 cases of cerebral tumour collected from the post-mortem records of Guy's Hospital. Ninety-nine of the cases occurred during the years 1872-84, both inclusive; the total number of necropsies was 5850, or about 450 a year, which gives 1 tumour of the brain for every 59 that come into the post-mortem theatre. Of the 100 cases, the growth was tubercular in 45, gliomatous in 24, sarcomatous in 10, carcinomatous in 5, gliosarcomatous in 2, cystic in 4, gummatous in 5, lymphomatous in 1, myxomatous in 1, and of doubtful nature in 3; 34 of the tubercular cases occurred in the male sex. There is much useful information in the paper, but the chief drift of the investigation was to ascertain, as far as possible, how many cases could have been treated surgically after the fashion of recent times. The conclusion was arrived at that only 3 of the tuberculous cases could have been benefited by operation, that at the outside 6, and probably only 4, of the gliomata, 1 only of the sarcomata, none either of the carcinomata or of the gliosarcomata, perhaps 2 of the cysts, the myxoma, but not the lymphoma, and 2 of the doubtful cases. Therefore, of the whole number of cases 10 might certainly have been operated upon, and probably 14. It will not be forgotten that before this number could have been treated surgically it would have been necessary to diagnose the seat of the tumour, even so late in the case as shortly before the death of the patient would suffice, whilst, of course, earlier in their histories many others might have been operated on with good prospect of success.

THE HEALTH OF VICTORIA.

ACCORDING to the last report of the Central Board of Health of Victoria, that colony has to face an evil which it has cost this country many millions to overcome, even to the limited extent to which it has been dealt with. We refer to the pollution of streams. Complaint is made in the report that there is no sufficient power to deal with the steadily increasing pollution of streams by animals and by trade refuse. In the same paragraph dealing with this subject, the question of the filtration of potable waters is discussed, and there seems a tendency to put greater trust in filters than is justified in the present state of our knowledge of the relation of organisms to disease in the human subject. Whilst filtration has its value, it should never be relied on as capable of removing the specific poison of such a disease as enteric fever from a potable water. Enteric fever is practically endemic in Melbourne, and with the first quarter of the year an outbreak may generally be looked for. It is most probably connected to an important extent at least—with the contamination of water-supplies that are used for human consumption.

PROFESSIONAL THIEVES AND DOCTORS' HOUSES.

IT is well known that the houses of medical men offer too many facilities for the operations of professional beggars and thieves. It is not so well known how much trouble it gives them to bring the law to bear on such characters. *The Times* reported a few days ago the case of William Thomas, aged eighty, who had called at the house of Dr. Bateman, Longridge-road, Earl's-court, under the pretence of being a friend of a sister in India. He was admitted, and at one stage left in the room alone, from which he took a hypodermic syringe. Thomas and his methods have long been well known to the Society for repressing Mendicity. But he has been only three times convicted in well-nigh forty years. On this occasion Dr. Bateman had to attend in court on four or five successive days before the case was heard. It may now be hoped that Thomas's active criminal career is over. But the moral of such cases is to be more chary of leaving strangers alone in doctors' houses.

HOW TO EXTINGUISH COMMON PARAFFIN LAMPS.

WE say extinguishing *common* paraffin lamps advisedly, because all the better sorts are provided with a special apparatus for covering up the flame. It is wrong, perhaps dangerous, to blow down the chimney, and it is possibly little, if at all, less dangerous to turn the wick down suddenly. The best plan is to blow not down the chimney, but across the flame at the base of the chimney through the perforated wick chamber, and, of course, always in the direction of the slit through which the wick rises. A very little puff will suffice, and there is no danger in the act, because the flame is not driven down into the oil chamber but simply blown off the wick horizontally. Care must always be taken to blow in the direction of the slit, or a great deal of breath may be wasted in vain.

A BIRMINGHAM CORONER ON HOSPITALS.

SOME words are reported by the *Birmingham Daily Gazette* as used by the coroner in reference to hospitals which require explanation. At an inquest on an illegitimate child, which had been taken to a hospital, and not to a doctor, the coroner said, "these hospitals are curses instead of being a blessing, and I wonder people subscribe to them." Surely our contemporary has unintentionally misreported the coroner, or the coroner has spoken in haste. In this particular case it is probable that a doctor should have been consulted; but if a coroner allowed his disapproval of conduct in a particular case to lead him to such a deliverance on hospitals, he owes it to himself and to them to correct his hasty judgment by one more in accordance with the general sense of mankind.

FOREIGN PROFESSORIAL APPOINTMENTS.

Lille (Faculté Mixte). — M. Baudry, Agrégé of the Medical Faculties, has been appointed Professor of External Pathology.

Lyons (Faculté Mixte).—M. Fouchier has been appointed Professor of Clinical Obstetrics.

Montpellier (Faculté de Médecine).—M. Chalot, Agrégé of the Medical Faculties, has been appointed Professor of External Pathology. M. Sarda has been appointed Chief of the Medical Clinic, M. Diffre Chief of the Clinic for Diseases of Old Age, and M. Breton Chief of the Children's Clinic.

Strasburg.—Dr. Götte of Rostock has been nominated to the Professorship of Zoology.

Havana.—The chair of Pharmacy has become vacant by the death of Dr. Don Manuel Vargus Machuca.

THE Islington Board of Guardians have addressed a letter to the Local Government Board calling attention to the very inadequate accommodation provided by the Metropolitan Asylums Board for lunatic children, and at the next meeting of the Asylums Board an endeavour is to be made to induce the managers to utilise the Winchmore-hill Hospital for the purpose. This hospital was erected at an enormous cost, but has been disused for some time, and is accounted a very suitable place for the accommodation of imbecile cases, until the new wings now in course of erection at the asylum at Darenth have been completed.

THE *London Gazette* of the 21st inst. contains the texts of orders issued by the Privy Council relating to anthrax and rabies. The orders, which are applicable to England and Wales and Scotland, take effect on the 1st prox., and contain regulations respecting the duties of the police on receiving notice of the existence of either of the diseases, the public warning of such existence, the regulations of the local authority as to movement of the diseased animals and as to cleansing and disinfection, the obligations on owners, the destruction of the infected animals, and the disposal of the carcases.

WE much regret to record the death of Dr. Samuel Woodman, the trusted adviser of the late Sir Moses Montefiore, and a local physician of considerable reputation. About a month ago, the deceased proceeded to the Continent with the intention of visiting Switzerland, but at Nuremburg he contracted typhoid fever and returned at once to Ramsgate to die.

THE literature of medicine has just been enriched by the publication, under the Padre Checcucci's editorship, of the "Letters, Scientific and Familiar, of Francesco Puccinotti," whose great "History of Medicine" is a classic among his countrymen, and whose work in medical jurisprudence and in the etiology of epidemics is of European reputation.

THE great Congress of the Pharmacists of Italy, which but for the cholera would have been held two years ago, will now meet at Turin on the 4th of October next. Among the subjects on the discussion list are the new code of public health, the modifications to be effected in the university curriculum so as to admit of all pharmacists having an academic qualification, the prevention of abuses, and other means of elevating the standard of the profession. The directing committee has spared no pains for the accommodation of visitors, native and foreign.

AT a meeting of the Perthshire Medical Association on September 10th, specially called for the purpose of considering the representation of the profession in Scotland in the Medical Council, it was unanimously agreed to recommend the candidature of Dr. Sinclair, of Dundee, to the members of the Association.

MR. CROOKSHANK'S Practical Bacteriology has been published in French by M. Carré of Paris. It represents the English edition, revised, and augmented by an appendix of thirty pages upon Photomicrography, illustrated with four photomicrographs, reproduced by autotype in special colours, and woodcuts.

THE Governor of the Isle of Man has, it is reported, informed the members of the medical profession who reside under his jurisdiction that the fee of £1 1*s*. for a post-mortem examination by order of the coroner will in future be reduced to 10*s*.

DR. SYMES THOMPSON has chosen as his subject of the Gresham Lectures this year the Infectious Diseases of Childhood. The course will extend from Oct. 5th to the 8th inclusive.

THE Duke of Westminster, K. G., has consented to accept the office of president of the London Temperance Hospital, in the room of the late Mr. Samuel Morley.

THE Russian Consul in Kashgar reports that the epidemic which has broken out there is typhus, and not cholera, as at first believed.

THE Harveian Oration will be delivered by Dr. Pavy at the Royal College of Physicians on Monday, October 18th, at 4 P.M.

THE SANITARY CONGRESS AT YORK.

THE proceedings in connexion with the ninth annual Congress of the Sanitary Institute of Great Britain and Ireland were opened on the 21st inst., at York. The members of the institute attended service at the Minster in the morning after which a formal reception by the Lord Mayor followed by a luncheon, was held. In the afternoon the Lord Mayor opened a Health Exhibition in connexion with the Congress. The exhibits are divided into five sections—(1) building materials, construction, and machinery; (2) water-supply and sewerage; (3) heating, lighting, and ventilation; (4) personal hygiene, foods, and disinfectants; and (5) miscellaneous. The Exhibition will remain open until the 16th prox.

In the evening the inaugural meeting of the Congress was held in the grand saloon of the Yorkshire Institute, where there was a large attendance to hear Sir T. Spencer Wells deliver his presidential address, an abstract of which we publish in another column.

On the 22nd inst., Professor F. de Chaumont, the chairman of the section of Sanitary Science and Preventive Medicine, gave an address, in which he treated of the germ theory of disease. A paper on the Economy of Cremation

Digitized by Google

was then read by Mr. W. Eassie, and Mr. W. Robinson followed with a paper on Beauty and Health *versus* Horror and Decay in our Cemeteries. Sir T. Spencer Wells opened the discussion, and expressed his approval of cremation. Several other members having spoken, Mr. Eassie replied, and the Conference adjourned.

In the afternoon, the Congress was resolved into a conference of medical officers of health. The following papers were read:—The Tenure of Office and Appointment of Medical Officers of Health, by Dr. R. Bruce Low; the Notification of Infectious Diseases, by Dr. Edward Seaton; Organisation and Administration for the Control of Infectious Diseases, by Mr. F. J. Sykes; and Hospitals for Infectious Cases—should they be Free or a Charge made for Maintenance? by Mr. Francis Vacher. A brief discussion followed the reading of these papers.

In connexion with the Health Exhibition, of which mention has previously been made, medals were awarded, amongst other exhibitors, to the following: to Dr. Jaeger's Sanitary Woollen System, London, for sanitary clothing; to Messrs. Ward and Co., Bradford, for sanitary clothing; and to the Doeker Hospitals and Huts Factory, London, for portable hospital. Certificates of exhibits for which medals had been previously given were awarded to F. C. Calvert and Co., Manchester, for disinfecting carbolic acid; W. Lyon, London, for steam disinfector; Morrell's Sanitary Appliance Company, Manchester, for portable cinder-shifting ash-closet; and Moule's Earth-closet Company, London, for earth-closet.

SANITARY IMPROVEMENTS IN NEWCASTLE-ON-TYNE.

TWELVE years have elapsed since THE LANCET Sanitary Commissioners paid their visit to Newcastle-on-Tyne, when collecting materials for their Report on the "Health of Operatives engaged in Chemical Manufactories." At the time our Commissioners were conducting their inquiries in the town and neighbourhood, Newcastle was passing through a severe crisis. The death-rate had risen to an unprecedented height, caused chiefly by an extremely fatal epidemic of scarlet fever, but also by the prevalence of other diseases, such as erysipelas, low forms of pneumonia, &c., attributable to defective sanitation. So deplorable was the state of things that the Local Government Board had sent down an inspector to make a special report on the condition of the town, and it will be remembered that Dr. Gwynne Harries, who was the gentleman appointed to conduct the inquiry, succumbed to scarlet fever, contracted shortly after his arrival at Newcastle. Under such circumstances it was natural that our Commissioners should interest themselves in the sanitary condition of the town, though the original inquiry was limited to the influence of certain occupations upon the health of the operatives engaged. Under the guidance, therefore, of Mr. H. Armstrong, the then recently appointed officer of health, they made themselves acquainted with the chief features of the case and most of the existing evils, and truly these were most discouraging, and sufficient to dishearten those who were then setting to work to remedy past neglect and to construct plans for permanent sanitary improvement. During the past fourteen years, however, the sanitary progress has been very great, and the old town of Newcastle may be spoken of as almost a new city. Over £220,000 have been expended by the Corporation in effecting the necessary improvements. Of this, £69,000 have been spent in dealing with insanitary dwellings under the Local Improvement Acts, and £20,000 for the erection of a new hospital for infectious diseases, exclusive of the cost for land. Baths and washhouses have cost £45,000, whilst no less than £85,000 have been expended on parks and open spaces. In addition to this, the town is now abundantly supplied with water, which is much above the quality of the old supply, and it is now proposed to deliver this water by tap on each landing of every tenement dwelling in the city. In 1884 a house-to-house visitation resulted in the issue of upwards of 12,000 notices for defects of various kinds, nearly all of which were remedied satisfactorily. Owing, no doubt, to the improvement of the tenement property, there is very little overcrowding of rooms; thus, out of 13,329 tenements in the city, there were only 362 instances in which the cubic space per person was less than 300 cubic feet each. The system of refuse removal has been much improved, the old privy middens are being abolished in favour of waterclosets, and the ordinary day refuse and ashes are now for the most part removed twice a week in tubs—a system which might well be tried in London. But, above all, the Corporation of Newcastle deserve the greatest credit for their energy in providing in the most complete manner, accommodation for coping with infectious diseases. In 1882 they obtained the power for the notification of such diseases, and the operation of this has been highly advantageous, since many outbreaks have been dealt with at their inception. At the present time ninety beds afford accommodation for small-pox and fever cases, and this, when the new hospital which was in course of erection is completed, will be brought up to 132 beds. In addition to this, the Port Sanitary Authority will shortly have a floating hospital for the isolation of infectious cases brought to the town by the river. The success that has been obtained at Newcastle in the sanitary campaign is, no doubt, in great measure due to the untiring zeal and energy of the health officer, Mr. H. Armstrong, but his efforts would have been of little avail—as we have had sad examples elsewhere—but for the hearty co-operation of the people of Newcastle and their representatives in the Corporation. Much money has been expended, no doubt, but it has been well spent, not frittered away; and Newcastle, with its new water-supply, good tenements, magnificent baths and washhouses, and its extensive and beautiful parks, can show an example to any town in the kingdom.

PRIZES AND SCHOLARSHIPS IN THE METROPOLITAN MEDICAL SCHOOLS.

THE following is a list of the Scholarships and Principal Prizes gained at the various Metropolitan Schools of Medicine during the session 1885-86:—

ST. BARTHOLOMEW'S HOSPITAL.—Lawrence Scholarship and Gold Medal: H. Davidson. Brackenbury Medical Scholarship: H. J. Tylden. Brackenbury Surgical Scholarship: A. Lyndon. Senior Scholarship in Anatomy, Physiology, and Chemistry: G. Heaton. Open Scholarships in Science: H. R. Jones, J. Kerr, and C. R. Stevens. Preliminary Scientific Exhibition: E. J. P. Olive. Jeaffreson Exhibition: J. Williamson. Kirkes Gold Medal: W. N. Hamer. Hichens Prize: F. S. Locke and F. S. J. Lulham. Wix Prize: Magnus Olaf Manson. Harvey Prize: B. Pierce. Junior Practical Anatomy (Treasurer's Prize): G. L. Rolleston. Senior Practical Anatomy (Foster Prize): B. Pierce. Junior Scholarships: G. L. Rolleston, W. M. A. Eccles, and W. F. Oakshott.

CHARING-CROSS HOSPITAL.—Llewellyn Scholarship, Certificate, and £25, J. G. Victor Sapp. Golding Scholarship, Certificate, and £15: P. J. Duncan. Governor's Clinical Gold Medal: Ernest A. Snape. The Pereira Prize, Certificate, and £5: G. O. Richards and Ernest A. Snape (equal). Senior Anatomy—Silver Medal: A. E. Baker. Junior Anatomy—Bronze Medal: Charles Gibbs. Senior Physiology—Silver Medal: P. J. Duncan. Physiology—Silver Medal: J. F. Colyer. Practical Physiology—Silver Medal: B. F. Jackson. Chemistry—Silver Medal: Charles Gibbs. Practical Chemistry—Silver Medal: Charles Gibbs. Medicine—Silver Medal: J. G. Victor Sapp. Practical Medicine—Silver Medal: J. G. Victor Sapp. Surgery—Silver Medal: J. G. Victor Sapp. Practical Surgery (Prize, a Minor Surgery Operating Case): G. O. Richards; Silver Medal: J. G. Victor Sapp. Botany—Silver Medal: P. J. Duncan. Materia Medica—Silver Medal: P. J. Duncan. Midwifery—Silver Medal: J. S. W. Chitty. Forensic Medicine—Silver Medal: J. S. W. Chitty. Pathology—Silver Medal: J. G. H. Carter. Dental Surgery—First Prize, Certificate, and £6 6*s.*: F. M. Ludbrook; Second Prize, Certificate, and £4 4*s.*: J. F. Colyer.

ST. GEORGE'S HOSPITAL.—Scholarship, value £125, open to sons of medical men: James McEnery. William Brown Exhibition, £100 per annum, tenable for two years: Arthur Heygate Vernon. Brackenbury Prize in Medicine: William Lee Dickinson. Brackenbury Prize in Surgery: Henry Goodale. Treasurer's Prize: William Lee Dickinson. Thompson Medal: Humphrey Wheeler. Sir Benjamin Brodie's Prize in Clinical Surgery: Henry Goodale. Acland Prize in Clinical Medicine: William Lee Dickinson. Henry Charles Johnson Memorial Prize in Anatomy: Cyril Ogle.

Digitized by Google

Pollock Prize in Physiology: Cyril Ogle. Sir Charles Clarke's Prize for Good Conduct: Hugh Lawson. First-year Proficiency Prize: Lionel William Seymour. Second-year Proficiency Prize: William Marshall Davidson. Third-year Proficiency Prize: Ernest Le Cronier Lancaster.

GUY'S HOSPITAL.—Treasurer's Gold Medal for Clinical Medicine: John Wychenford Washbourn. Treasurer's Gold Medal for Clinical Surgery: Frédéric François Burghard. Gurney-Hoare Prize for Clinical Study: Richard Moody Ward. Beaney Prize for Pathology: John Wychenford Washbourn. Mackenzie Bacon Prize for Ophthalmoscopy: Sidney Wacher. Mackenzie Bacon Prize for Nervous Diseases: Edward Wilberforce Goodall. Burdett Prize for Hygiene: William Henry Bowes. Sands Cox Scholarship: Alfred Parkin. Michael Harris Prize for Anatomy: Alfred Parkin and Robert Devereux Mothersole (equal). Fourth-year Students: Frédéric François Burghard, first prize; Francis Stanhope Hawkins, second prize. Third-year Students: Arthur Edward Poolman, first prize; Ernest Henry Starling, second prize. Second-year Students: Alfred Parkin, first prize; Robert Devereux Mothersole, second prize. First-year Students: Frederick William Hall, prize (£50).

KING'S COLLEGE.—Winter Session.—Anatomy: Thomas Boswell Beach. Physiology: Peyton Todd Bowman Beales. Chemistry: Herbert Stanley Ballance. Comparative Anatomy: John Henry Leonard. Surgical Clinical (Professor Wood): Charles Drinkwater. Surgical Clinical (Professor Lister): Arthur E. Hensley. Medicine: Philip Henry Hensley and Jeremiah Penney (equal). Surgery: Charles Drinkwater. Clinical Medicine: Francis William Jollye. Summer Session.—Practical Physiology: James John N. Merris. Practical Biology: Hamilton Ashley Ballance. Botany: Arthur Robert Savell. Forsenic Medicine: Robert James Carter. Obstetric Medicine: Robert James Carter. Materia Medica: Richard Tanner Hewlett.

LONDON HOSPITAL.—Entrance Science Scholarships for proficiency in the subjects required for the Preliminary Scientific M.B. Examination at the University of London. £60 Scholarship: D. Brown. £40 Scholarship: J. N. Collins. Buxton Scholarships for proficiency in the subjects required for the preliminary examinations—£30 Scholarship: T. Jones. £20 Scholarship: Y. H. Mills. Clinical Medicine—£20 Scholarship: G. C. W. Wright. Clinical Surgery—£20 Scholarship: H. G. Lys. Clinical Obstetrics—£20 Scholarship: L. C. E. Calthrop. Letheby Prize for proficiency in Chemistry—£30: J. S. Hicks. Anatomy and Physiology—£20 Scholarship: D. Brown. Dressers' Prizes for zeal, efficiency, and knowledge of minor surgery—£15 Prize: O. M. Jones. £5 Prize: W. H. Coates.

ST. MARY'S HOSPITAL.—Scholarships in Natural Science of £60 each: G. A. Simmons and G. Watson. Scholarships in Natural Science of £50 each: C. E. Lansdowne, H. A. Caley, and W. Low. Scholarship of 50 guineas for students from Epsom College: J. J. Knox. Exhibitions in Natural Science, of £30 each: A. R. Chater and H. F. Mantell. Scholarship in Pathology: J. J. Clarke, W. Williams, and S. A. Tidey. Summer Session, 1885, second year—Midwifery: J. T. Bays. Medical Jurisprudence: J. T. Bays. First year—Materia Medica: F. W. Lewitt. Botany: F. W. Lewitt. Practical Chemistry: F. W. Lewitt, A. Hickley, P. J. Kingston, and W. S. Sharpe (all four equal). Winter Session, 1885-86, third year—Medicine: H. C. Barr and H. S. Collier (equal). Surgery: H. S. Collier. Practical Surgery: H. S. Collier. Pathology: H. F. Collier. Third and fourth years—Clinical Medicine: E. Callender and H. C. Phillips (equal). Clinical Surgery: H. C. Barr and G. Spear (equal). Ophthalmology: E. Evans and J. J. Clarke. Second year—Anatomy: A. Lewers. Physiology: F. W. Lewitt. First year—Anatomy: A. E. Shaw, first prize; G. Watson, second prize. Physiology: H. A. Caley, first prize; A. E. Shaw, second prize. Chemistry: G. A. Simmons. Special prizes for first-year students for proficiency in Anatomy, Histology, Materia Medica, and Chemistry: F. W. Lewitt. For second-year students for proficiency in Anatomy, Physiology, Midwifery, and Medical Jurisprudence: J. T. Bays. For third-year students for proficiency in Medicine, Surgery, Pathology, and Operative Surgery: W. Holloway.

MIDDLESEX HOSPITAL.—Broderip Scholarships for the best examination at the bedside and in the post-mortem room: First, W. G. Nash; second, W. B. Cockill. Governor's Prize: E. E. Lewis. Hetley Prize: W. B. Cockill. Murray Medal and Scholarship: W. G. Nash. Exhibition in Anatomy: First year: J. K. Clarke; Lyell Medal, E. T. Larkham. Class Prizes—Medicine, W. G. Nash. Surgery: Kershaw. Practical Medicine: W. G. Nash. Practical Surgery: H. Baldwin. Anatomy: J. A. Hutton. Dissections: C. E. Bennett. Physiology: J. K. Couch and T. H. Clarke. Chemistry: C. H. Fazan. Midwifery: E. E. Lewis. Forensic Medicine: J. E. Hancock. Pathological Anatomy: W. H. Vickery. Materia Medica: H. A. Daniel. Practical Chemistry: H. A. Daniel and C. H. Fazan (equal). Botany: C. H. Fazan. Practical Physiology: H. A. Daniel. Comparative Anatomy: Mr. Strong. Entrance Scholarships: First, R. A. Earle; second, F. A. Wagstaff. Summer Entrance Scholarship: F. Harsant.

ST. THOMAS'S HOSPITAL.—Summer Session, 1885.—First-year Students: F. C. Abbott, College Prize, £15, and Certificate; T. P. Cowen, College Prize, £10, and Certificate. Second-year Students: Charles Henry Eccles, College Prize, £15, and Certificate; E. Webster and E. H. Wright (equal), College Prize, £10, and Certificate. Third-year Students: S. W. Wheaton, College Prize, £15, and Certificate; and H. J. Macevoy, College Prize, £10, and Certificates (equal). Winter Session, 1885-86.—Entrance Science Scholarships: A. F. Stabb, Scholarship, £100, and Certificate; S. G. Toller, Scholarship, £60, and Certificate. First-year Students: A. F. Stabb, the William Tite Scholarship, £30, and Certificate; A. C. Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Birmingham Urban District.—The quarterly report for the period ending July 3rd last shows that the sanitary work of the health department continues to be vigorously prosecuted. Dr. Alfred Hill reports that over five thousand notices for the abatement of nuisances were issued, and that 1126 infected articles were dealt with at the disinfecting station. One small-pox patient and 98 cases of scarlet fever were isolated in one or other of the borough infectious hospitals.

Nottingham Urban District.—After paying a well-merited tribute to Dr. Seaton, his predecessor in the office of health officer, Dr. Whitelegge gives the population of the borough during 1885 as 211,424, with a birth-rate of 34·5 and a death-rate of 18·2 per 1000 living, the death-rate being the lowest on record. The death-rate from the so-called seven principal zymotic diseases was 2·2 per 1000, the average for the preceding seven years having been 3·4. Pointing to a reduction which has been steadily taking place in the scarlet-fever mortality, Dr. Whitelegge reminds his authority that one of the results of this reduction is that the number of protected survivors is becoming less and less. Epidemics of this disease are certain to recur, and the next one in Nottingham will find a much larger number of susceptible persons than during the past few years, the available material in which the epidemic will work being added to year by year by births. Hence it is that during the intermissions sanitary authorities should prepare in advance the means of staving off epidemics. Referring to the compulsory notification of infectious diseases, it is stated that this principle has now been adopted by thirty-nine English communities. In Nottingham it is shown that one principal result attained has been a reduction in the ratio of deaths to known cases, and this is significantly shown in a tabular form. The decline in the deaths commences with the commencement of compulsory notification; the decline is continuous, and it has reached a point considerably below the usual level of non-epidemic years. As regards scarlet fever, the diminution is greater than that which has obtained throughout the country generally, and it has been markedly constant in the notified diseases, whilst it has not taken place as regards other infectious diseases. And this result, it is contended, has been brought about by means of the improved sanitary administration and control of infection which has become possible by reason of it; and amongst other things it is pointed out that notification has led to disinfection being now a reality. It is also stated that the system has caused no disturbance of the relations between medical men and their patients, nor has it led to concealment of disease and the employment of unqualified practitioners, as was anticipated by some. An important improvement is reported as regards the hospital for infectious diseases, a large site having been obtained for the erection of an entirely new permanent set of buildings. The pail-system of excrement removal has reached an important position in Nottingham; 1100 new ones were provided in 1885, raising the total number of these substitutes for the old midden-privy to no less than 32,786. This form of closet is said only to fail where the habits of the people are utterly degraded.

Sheffield Urban District.—In common with a majority of the towns and districts of England, Sheffield had an exceptionally low death-rate last year—namely, one of 20·6 per 1000; and it is pointed out that, had the rate for the previous ten years remained in operation, no less than 887 more lives would have been sacrificed. But Dr. Sinclair White very properly warns his authority against claiming that the reduction is entirely due to sanitary reforms effected in the condition of the borough. The population in 1885 is estimated at 305,870, the birth-rate being 35·1 per 1000, and the deaths under one year of age amounting to 163·8 per 1000 registered births. One of the most interesting parts of the report relates to the mortality amongst those occupied in the various local trades, the idea of placing this on permanent record being evidently taken from Dr. Ogle's report to the Registrar-General. As yet, of course, the record is limited to one year, but when the tables have been prepared for a series of years they will certainly furnish valuable data on this subject. The summary amount of action taken to stay the spread of infectious diseases shows that there has been considerable activity in this matter, and Sheffield may be congratulated on having at least a very valuable instalment of permanent hospital provision, and in carrying out with energy the work of disinfection. The canal boats, slaughter-houses, common lodging-houses, offensive trades, dairies, &c., are kept under supervision, and an account is given of the work undertaken in the departments dealing with the adulteration of food and drugs, and with smoke abatement. Adverting to a special report on lead-poisoning by water, which we noticed last week, and to the fact that the danger of such poisoning was done away with by allowing the water to pass over broken lime-stone, Dr. White refers to the desirability of maintaining some such action as will diminish the scarcity of lime-salts in the water, such scarcity favouring the rickety deformities which are numerous in the town.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5775 births and 3942 deaths were registered during the week ending Sept. 18th. The annual death-rate in these towns, which had steadily increased in the preceding five weeks from 18·9 to 22·6, was again 22·6 last week. During the first eleven weeks of the current quarter the death-rate in these towns averaged 20·3 per 1000, and was 1·1 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 14·9 in Bristol, 15·3 in Derby, 17·1 in Huddersfield, and 17·6 in London. The rates in the other towns ranged upwards to 33·8 in Salford, 36·0 in Portsmouth, 39·6 in Preston, and 40·8 in Norwich. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had increased in the previous five weeks from 717 to 1199, were last week 1132; they included 925 from diarrhœa (exclusive of 26 attributed to simple cholera), 58 from "fever" (principally enteric), 49 from whooping-cough, 43 from scarlet fever, 82 from measles, 25 from diphtheria, and not one from small-pox. The lowest death-rates from these zymotic diseases were recorded last week in Bristol, London, and Derby; and the highest in Hull, Portsmouth, and Norwich. Diarrhœa caused the highest death-rates in Bolton, Portsmouth, Sunderland, Hull, and Norwich; "fever" in Cardiff and Portsmouth; scarlet fever in Birkenhead; Salford, and Blackburn; whooping-cough in Oldham; and measles in Nottingham. The 25 deaths from diphtheria included 13 in London, 3 in Birmingham, 3 in Liverpool, and 2 in Manchester. Small-pox caused no death in London and its outer ring, or in the twenty-seven large provincial towns. Only one small-pox patient was under treatment in the metropolitan asylum hospitals situated in and around London on Saturday last. The deaths referred to diseases of the respiratory organs in London, which had been 160, 128, and 110 in the preceding three weeks, rose last week to 168, but were 14 below the corrected average. The causes of 63, or 1·6 per cent., of the deaths in the twenty-eight towns last week were not certified either

Digitized by Google

by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Portsmouth, Brighton, Preston, and in four smaller towns. The largest proportions of uncertified deaths were registered in Oldham and Liverpool.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·7, 19·4, and 20·6 per 1000 in the preceding three weeks, declined again to 18·8 during the week ending September 18th; this rate was 3·8 below the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 11·8 and 13·9 in Greenock and Edinburgh, to 20·8 in Paisley and 24·1 in Glasgow. The 465 deaths in the eight towns last week showed a decrease of 43 from the number in the previous week, and included 45 which were referred to diarrhœa, 11 to whooping-cough, 7 to scarlet fever, 6 to "fever" (typhus, enteric, or simple), 3 to diphtheria, 1 to measles, and not one to small-pox; in all, 73 deaths resulted from these principal zymotic diseases, against numbers increasing from 63 to 93 in the preceding five weeks. These 93 deaths were equal to an annual rate of 3·0 per 1000, which was 3·5 below the mean rate from the same diseases in the twenty-eight English towns. The deaths referred to diarrhœa, which had risen in the previous four weeks from 23 to 57, declined again last week to 45, of which 19 occurred in Glasgow, 8 in Dundee, and 5 in Paisley. The annual death-rate from diarrhœa in the eight Scotch towns last week did not average more than 1·8 per 1000, whereas the mean rate from the same cause in the twenty-eight English towns was 5·3. The fatal cases of whooping-cough, which had been 19, 10, and 20 in the preceding three weeks, declined again last week to 11, and included 6 in Glasgow and 2 in Edinburgh. The 7 deaths from scarlet fever corresponded with the number in the previous week, 6 being returned in Glasgow. The deaths referred to "fever," which had been 7 and 4 in the previous two weeks, were 6 last week, of which 3 occurred in Paisley and 2 in Glasgow. Two of the three fatal cases of diphtheria, and the fatal case of measles, were returned in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 56 and 72 in the previous two weeks, declined again last week to 65, and exceeded by but one the number in the corresponding week of last year. The causes of 60, or 13 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 18·2, 26·2, and 25·9 per 1000 in the preceding three weeks, further rose to 27·5 in the week ending Sept. 18th. During the first eleven weeks of the current quarter the death-rate in the city averaged 21·7; the mean rate during the same period was 19·1 in London and 17·8 in Edinburgh. The 186 deaths in Dublin last week showed an increase of 11 upon the number in the previous week, and included 29 which were referred to diarrhœa, 5 to "fever" (typhus, enteric, or simple), 2 to scarlet fever, 2 to diphtheria, 1 to whooping-cough, and not one either to small-pox or measles. Thus 39 deaths resulted from the principal zymotic diseases, against 18, 22, and 38 in the preceding three weeks; they were equal to an annual rate of 5·8 per 1000, the rates from the same diseases last week being 3·1 in London and 1·4 in Edinburgh. The fatal cases of diarrhœa, which had been 9, 14, and 26 in the previous three weeks, further rose last week to 29, and exceeded the number in any previous week of this year. The 2 deaths from scarlet fever showed a decline of 5 from the number in the previous week, while the 5 from "fever" exceeded the number in the previous week by 1. Three inquest cases and 4 deaths from violence were registered; and 39, or more than one-fifth of the deaths, were recorded in public institutions. The deaths of infants showed a further considerable increase upon recent weekly numbers, while those of elderly persons had further declined. The causes of 33, or nearly 18 per cent., of the deaths registered during the week were not certified.

A HOMŒOPATH SUED BY A PHARMACIST.—A pharmacist has successfully sued a homœopathic doctor in Játiva, for illegally trenching upon his province by preparing and supplying medicines in the form of globules to his patients.

THE SERVICES.

INDIA OFFICE.—The Queen has approved of the retirement from the Service of the undermentioned officers of the Staff Corps and Indian Military Forces:—Brigade Surgeon James Browne, M.D., of the Bengal Medical Establishment, and Surgeon-Major Charles Robert George Parker, of the Madras Medical Establishment. The undermentioned officers have been granted a step of honorary rank on retirement:—Surgeon-Major Charles Robert Parker, of the Madras Medical Establishment, and Surgeon-Major Theophilus Bolton Wright Plunkett Johnston, of the Bombay Medical Establishment, to be Brigade Surgeons.

ADMIRALTY.—The following appointments have been made:—Staff Surgeon Wm. H. Colahan, to the *Canada;* Staff Surgeon Joseph Wood, to the *Assistance;* Staff Surgeon Anthony Gorham, to the *Shannon;* and Surgeon Patrick B. Handyside, to the *Canada.*

YEOMANRY CAVALRY.—Westmoreland and Cumberland: Surgeon and Honorary Surgeon-Major Joseph Wickham, M.D., the resignation of whose commission has already been announced, is permitted to retain his rank, and to wear the uniform of the regiment on his retirement.

Correspondence.

"Audi alteram partem."

DIRECT REPRESENTATION OF THE PROFESSION ON THE GENERAL MEDICAL COUNCIL.

To the Editor of THE LANCET.

SIR,—The great majority of our profession will agree with the opinion, given in the annotation in THE LANCET of Sept. 18th, that 343 responses cannot represent 17,000 practitioners, and that the meeting at Birmingham was a failure; and will also agree with the hope, expressed in that article, that the promoters will not seriously prosecute their well-intentioned labours.

Let me call attention to what took place at Birmingham. A meeting was called of a committee (self-constituted, and not in the least representative). Of the 343 members of that committee only thirty-two attended, and towards the end of the meeting only a few remained. It was then agreed to send the names of a number of the candidates to the whole committee, for each one to select three names, the three having the largest number of recommendations to be adopted by the committee. Now, Sir, in what way is that plan to recommend itself to the whole profession, each member of which is just as capable of forming a correct judgment on the merits of each candidate as is any one of the 343 who are not the elected representatives of the profession with power to select candidates? Looking at the matter from every point of view, is it not substituting a body of 343, self-constituted as a committee, for the whole 17,000 members of the profession? For my own part, I think the system of committees a wrong one. The profession now, for the first time, is given a direct representation on the Medical Council, and the Council will send out the names of all the candidates to the 17,000 electors, for them to return three of those candidates to represent them. The members of the medical profession for the first time form an electoral body, unequalled in education and intelligence by any other in the kingdom, and recourse to anything like the ordinary electioneering tactics will be simply an insult to the understanding of those composing that electorate. I ask is it seriously thought to be necessary for any committee to inform the 17,000 electors of the merits of the majority, if not the whole, of the candidates? Are they not thoroughly competent to decide each one for himself? The representation is intended to be direct. I ask, will it be direct if any committee, however influential or well-intentioned, should interfere between the candidates and the electorate?

I am, Sir, yours obediently,

Brighton, Sept. 18th, 1886. R. P. B. TAAFFE.

To the Editor of THE LANCET.

SIR,—After reading in THE LANCET an account of the meeting at Birmingham attended by only thirty-two members of the profession, I feel convinced that any choice of

Digitized by Google

candidates made by that meeting, or emanating from it, will be disregarded by the large body of electors upon whom will devolve the great and important duty of sending representatives to the General Medical Council. The Birmingham meeting was evidently a distinct failure; let us hope, however, that it will have the effect of impressing the minds of the electors with the solemn responsibility devolving upon each of them individually to select the best men out of those who offer themselves as candidates. I should think there can be no difference of opinion as to the importance of voting for general practitioners exclusively as our representatives at the forthcoming election. We do not want consulting practitioners—they already form a majority in the Council. We have before us the names of three good candidates (general practitioners): Dr. Morris of Spalding, Dr. Glover of London, and Dr. Dolan of Halifax. Can we do better than return them as our representatives?

I am, Sir, yours faithfully,

Dover, Sept. 20th, 1886. JOHN MARSHALL, L.R.C.P. Lond.

THE HOSPITAL FOR WOMEN, LIVERPOOL.

To the Editor of THE LANCET.

SIR,—I have diligently compared the various reports, and I find all agree with *The Times* (August 9th) that counsel's query to Dr. Grimsdale was, "What is the mortality of these operations at the hospital?" There was no reference to the year 1885, and no reason for such limitation. The operation in every case he approved of abdominal section, and that all four died in consequence of their operations—three within twenty-four hours, and one after eight days. Dr. Grimsdale, therefore, must rank among "the disciples of modern abdominal surgery," with a death-rate in 1885 of 100 per cent.

Dr. Grimsdale treats the inquiry committee as if it were the pliant eject of his own consciousness, bound to agree with his views. But I think it will not ignore the series of cases I have sent in, nor the large number of specimens of diseased ovaries and tubes which I have forwarded. It is by pathology, and not by committee, that the question will have to be solved. I have already shown between thirty and forty specimens at the Medical Institution. Numerous others I have exhibited at branch meetings in Chester, Southport, Ashton-under-Lyne, and North Wales. I think I have demonstrated the pathology of all the uterine appendages I have removed for inflammatory disease, except perhaps a dozen, before some public meeting of the medical profession. Dr. Grimsdale says that the operation of removal of the uterine appendages is a valuable addition to surgery, but liable to abuse. He considers, in fact, that my selection of suitable cases is imperfect. I am willing to learn. He has several times recommended it in consultation, and the excision has been performed in our hospital. I am willing to assume that his cases have been suitable, and only ask that he will forward his specimens to the inquiry committee as a standard for comparison. If he refuse to do this, I will not pretend to believe that his objections to my practice are wholly scientific.—I am, Sir, yours fathfully,

No. on register.	Date of operation.	Age.	Disease.	Operation.	Recovered.	Died.	Abdominal section.
166	July 9th	39	Myoma: left hæmatosalpinx, right hydrocystic ovary	Removal of uterine appendages	R	—	A.S.
179	July 20th	30	Pelvic hæmatocele; peritonitis	Drainage	R	—	A.S.

was performed on the plaintiff, Mrs. Casey, in 1884, and she was the sixth case of pelvic hæmatocele I had treated by abdominal section. Dr. Grimsdale has not replied to my question why he excludes these six cases and a successful case of removal of uterine appendages for hæmatosalpinx in 1884 from his calculations. I have published five of them in detail. He saw the second on my list in consultation, and was present at the operation. The Annual Report for 1884 is in his possession. His reply is that I mystify, but I will not retort.

I regret to be obliged to correct the report of cases of pelvic hæmatocele and of hæmatosalpinx treated by abdominal section in 1885, which Dr. Grimsdale has forwarded to you. He has omitted the two cases given in the above table.

I have already said that cases of hæmatosalpinx ought not to be classed with cases of intraperitoneal hæmorrhages, for they are entirely different; but if he quotes two he ought to quote all. In the second case I removed several pints of putrid blood from the peritoneal cavity of a woman who was carried into hospital apparently in a dying condition and with a temperature of 104°. Because there was no need to remove her ovaries and tubes, Dr. Grimsdale refuses to include it among my cases. But his objection is against abdominal section, and he has informed our hospital committee that these cases are invariably cured by rest. As regards the single death registered in 1885, I can only repeat that it was from morbus cordis, and in no way due to the operation, from which she had completely recovered; and in confirmation of this statement I refer with confidence to Dr. A. Samuels, physician to the Hospital for Consumption, who attended her during my absence at Cardiff and signed the certificate of death.

Dr. Burton has had only one case of pelvic hæmatocele under his care, and I notice that he treated it by a method which is universally condemned by recent authorities. He says he cannot diagnose them. I reply that among all classes of pelvic disease there is none that can be more surely diagnosed, but the indications can only be learned by experience.

Dr. Grimsdale says in his letter of August 28th that, so far as he knows, there were only four "real" consultations in 1885. I have, however, shown our committee that many more were held. But it is a fact that Dr. Grimsdale was called in consultation four times by a colleague. It is also a fact that

Liverpool, Sept. 21st, 1886. FRANCIS IMLACH.

To the Editor of THE LANCET.

SIR,—Dr. Burton is neither entitled to speak for me, nor to say that I am unable to answer for myself. Though I have not yet, since my illness, returned to active practice, I am quite capable of following the discussion in your columns, and I desire, from my personal experience, to express my approval of Dr. Imlach's method of treatment of pelvic hæmatocele. I am, Sir, yours faithfully,

R. J. LUPTON,
Acting Medical Officer, Hospital for Women.

Liverpool, Sept. 20th, 1886.

"SPAYING," OR REMOVAL OF THE UTERINE APPENDAGES?

To the Editor of THE LANCET.

SIR,—Mr. Lawson Tait's letter in your issue of Sept. 18th is chiefly occupied with his reply to your leader of Sept. 4th on the use of the term "spaying." His last paragraph he devotes to me, and in that portion of it in which he specially refers to my letter he gravely declares his opinion that it is just because the people understand this term "spaying" so well, and know what are its intentions and results on animals, that therefore no argument can be stronger against its use as a name for the corresponding operation in women—a *non sequitur* which is to me simply amazing. This popular knowledge of the word is, I consider, the convincing argument in its favour. I would ask, why should Mr. Tait write, as regards me, as he does in his letter of Sept. 18th, where he says, "I am not at all surprised at the row in Liverpool, and the unusual results brought about by it, now that we have an admission from Dr. Grimsdale of what he has been doing and saying." What the expression of my preference for the term "spaying" over Mr. Tait's phrase, with its unsound physiology, has to do with the row in Liverpool passes my comprehension. My arguments in favour of that term, it is true, may be, and probably are, weak as water in the esti-

Digitized by Google

mation of Mr. Tait, but at least they satisfy me and many leaders in the profession. And why should Mr. Tait think a row in Liverpool a necessary consequence of this? Mr. Tait continues: "When I heard him say in the witness-box that 'ovariotomy did not necessarily include removal of the ovary,' I suspected he was living in an atmosphere of confusion; now I know he has created it." Mr. Tait will probably begin to suspect that it was he who at that particular time was living in an atmosphere of confusion, and clearly of his own creation, when I tell him I did not, either in the witness-box or elsewhere, say that "ovariotomy did not necessarily include removal of the ovary." I was not asked by counsel on either side any question relating to ovariotomy. Mr. Tait further says: "In his evidence, Dr. Grimsdale clearly threw blame on Dr. Imlach for performing operations without consultations." This I deny. I answered the questions of counsel as to consultations truthfully, as I presume Mr. Tait will admit I was bound to do; but while in the witness-box I threw no blame on Dr. Imlach. Mr. Tait goes on to say: "If Dr. Imlach did this (i.e., perform operations without consultations), then Dr. Grimsdale was clearly to blame for it. As consulting officer to the hospital, he could have insisted on consultations being held, and if they had been refused, his remedy lay in an appeal to the committee of the hospital by a complaint that an important law was broken and defied." Mr. Tait will be glad to learn that I anticipated his valuable suggestions, and that the admirable course of action laid down by him is precisely that which I adopted so long ago as the beginning of February in this year. The only difficulty is that up to this time the committee have not made up their minds how to act to enforce the law so broken and defied. Finally, Mr. Tait says: "Instead of this, he appealed to outside authority in such fashion as led to most discreditable proceedings." This is exactly what I did not do.

Truly, Mr. Tait's knowledge of Liverpool medical affairs is at present not altogether accurate. He had better change his correspondent.—I am, Sir, yours obediently,

Liverpool, Sept. 18th, 1886. THOMAS F. GRIMSDALE.

*** The correspondence on the above subject must now cease.—ED. L.

SUBPERITONEAL HÆMATOCELE.

To the Editor of THE LANCET.

SIR,—In common evidently with many other members of the profession, I was very much surprised at the statement of Mr. Lawson Tait, in giving evidence in a recent case, that "95 per cent. of cases of subperitoneal hæmatocele are fatal without operation," the operation indicated being removal of the "uterine apendages." My attention was attracted to the statement by the following circumstances:—A few weeks ago I requested Dr. Stirton, of this city, to see a case with which I was unwilling for certain reasons to be professionally associated. A tumour in the right iliac region was diagnosed, and there was some uncertainty as to its nature. With the view of elucidating matters, Dr. Stirton inserted a fine trocar and cannula of Dieulafoy's aspirator. A small quantity of blood oozed through the trocar, but it had all the characters of effused blood, and a subperitoneal hæmatocele was at once pronounced to exist. Aspiration was immediately proceeded with, and about twenty ounces of dark fetid blood were removed without difficulty. Rest being enforced, the patient passed about ten days in bed without a bad symptom. After that time she got up, and very soon resumed her household duties, to which she has been attending since without the slightest symptom of ill-health. Is it in such cases as this that Mr. Lawson Tait, and those who think with him, would proceed to the performance of so grave an operation as that of removal of the "uterine appendages"?

On referring to an admirable book which I have beside me ("Traité pratique des Maladies de l'Uterus et de ses Annexes,") by Nonat, I find the following opinions on this subject. "Peri-uterine hæmatocele terminates rarely in death." In referring to the terminations of hæmatocele, this authority points out how at the menstrual period the symptoms are aggravated; and a second cause of recrudescence is noted as arising from the process of absorption, which Dupuytren has compared to that of digestion. Left to itself, three methods of termination are noted: first, by absorption of the effused blood; second, by evacuation by either the rectum or the vagina; and thirdly, by effusion into the peritoneal cavity if the hæmatocele be subperitoneal. Fatal results rarely take place when by the second method the tumour is incompletely evacuated, and inflammatory phenomena and septicæmia ensue. The termination by effusion into the peritoneal cavity, while grave, is also maintained to be very rare. Hæmatocele may cause death, but according to Nonat that result is rare. In fifteen cases of undoubted hæmatocele which came under his observation but one resulted in death, and this was associated with tubal pregnancy. In suitable cases, Nonat is in favour of the treatment of hæmatocele by puncture. Now, if simple puncture (aspiration) of a hæmatocele gives such favourable results, surely the exigencies demanding the formidable operation of removal of the uterine appendages must be rare indeed. I am one of those who believe that a highly culpable amount of surgical interference with the uterus and its appendages obtains in these days, that many lives are sacrificed in this manner at the shrine of "brilliant surgery," and that the recent reprobation of such interference is justly merited. Of course all this is quite apart from sympathy for Dr. Imlach, as it must not be forgotten that it is a very simple matter for the most careful, the most skilful, and the most conscientious to become entangled in the meshes of the law.

I am, Sir, faithfully yours,

Glasgow, Sept. 4th, 1886. D. CAMPBELL BLACK.

NATURE AND TREATMENT OF FLAT-FOOT.

To the Editor of THE LANCET.

SIR,—Mr. Mayo Collier contends that because a movement forwards of the astragalus on the os calcis is impossible when the sole is resting on a horizontal surface, therefore the flattening of the foot is primarily due to an alteration in the position of the latter bone caused by raising the heel above the level of the sole, as is done by the conventional boot. While fully agreeing that the deformity is not due to laxity of the ligaments, I would point out some objections to his view of the cause and to the treatment, based on that view, which he proposes.

The astragalus does not in flat-foot move forwards so much as downwards and inwards. Prof. Humphry has described in THE LANCET of March 20th, 1886, a dissected specimen then before him. Moreover, take an ordinary case of incipient valgus, of weak ankles, as it is called—always to be easily found where children are,—and let the subject stand barefooted on a level surface, with the full weight of the body on one foot: then raise the anterior part by placing the hand beneath, or by any imitation of the sole which Mr. Collier describes; it will be seen that the deformity is not diminished. Now let the child spring on tiptoe; it will be seen that the arch is distinctly improved. Why? Because the heel is raised, and the body supported in that position, not only, as commonly stated, by the muscles acting on the heel, but also by the tibialis posticus, the long flexors, and the peronei. The tendons of these muscles can be felt as they start out behind either malleolus, and they are, in relation to the arch, as bow-strings to a bow: the ligaments are thus relieved of the heavy strain which the weight of the body would otherwise throw on them. It is by this agency that the arch of the foot is maintained in good walking.[1] By this agency, indeed, the arch, which hardly exists in infancy, is formed, and by it, and by it alone, can the structure in a satisfactory and permanent manner be restored.

I say, then, that as much vigorous but well-directed exercise as can be properly borne, and not "as much rest as possible," is the right treatment. The patient should when sitting, or better when lying, be directed to forcibly invert the foot, and flex the toes as much and as often as can be done; the surgeon or nurse should occasionally see how much resistance can be overcome in doing this. He (or, as is more likely, she) should learn as soon as possible to spring up on tiptoe, sustaining the position awhile and then gradually sinking on the heel, and should learn, if he must stand, to stand on the toes. To raise a weight by means of a cord running over pulleys is, for the purpose in view, of all exercises the best; the object is that the weight

[1] I discussed at length the Physiology of the Feet in an article in THE LANCET of June 28th, 1884.

Digitized by Google

shall partly support the body as the latter rises to extreme tiptoe; then the toes *must* grip the ground for the downward pull. The inspiration, I may add, should go with the upward, the expiration with the downward, movement. The act of turning a wheel fixed so high that the handle can only be reached with difficulty when at the highest point of the circle is a similar exercise, and may be used with the same object. The patient should learn, as soon as may be, to walk with a springy gait, and then do it freely, avoiding fatigue. The toes should come to the ground the moment before the heel reaches it—this can only be done properly in boots without heels; the heel should then be vigorously raised with the onward movement, the toes firmly gripping the ground. Thus the very act of walking is made a means of cure. This, in my judgment, is the way to treat flat-foot, but to raise the anterior part by "a sole quite an inch thick, fining off to a line or two at the heel" would be to place the foot in a most unnatural position, and, by preventing the necessary bending at the metatarso-phalangeal joints, would be fatal alike to good walking and to the restoration of a lost plantar arch.

High heels to boots, bad as they are, and that for many reasons, do not necessarily tend to cause flat-foot, and only do so when the bowstring action of the flexors is arrested by the fixed position of the toes, as in pointed boots, or when the weight of the body is rested on the high heel. A French woman's idea of a high heel is not to use it. The observant Max O'Rell says that an English lady in walking bears on the heel, a French lady on the point of the toes;[2] and I have seen it gravely stated that French ladies practise walking with an indiarubber ball fitted with a squeak, and fixed, one under each heel, the object being to avoid making the sound which pressure on the ball would cause. They who habitually stand and walk on tiptoe will never be flat-footed. This, as Sir James Paget has told me in support of my views, was the dictum of a dancing master at Windsor he had known many years ago. I am sure that it is true.

As a protest against an operation described by Professor Ogston, I published in THE LANCET of Feb. 9th, 1884, an account of two extremely bad cases cured by muscular action which had then stood the test of ten years of active life, the condition being now still maintained. Of one, the result of direct violence, I am myself the subject; the other, an ordinary but very severe case caused by prolonged standing and supporting a heavy weight, could, and still may, be identified in London.

I do not say that Mr. Collier's own "novel departure in the treatment of flat-foot" is one of those inventions of which the fascination of novelty and not necessity is the mother (to still use his own words), but I do claim that a very stern necessity prompted my investigations. I had, after an accident in 1867, been for six years a cripple condemned to go about in constant discomfort, often in severe pain, compelled, excepting at short intervals, to wear a cumbrous apparatus, and found myself little, if any, better off at the end of the sixth than at the end of the first year, in spite of the best surgical advice and the best mechanical assistance. In despair at having again to go through the misery of bringing into something like comfort a renewed mechanical "boot," I boldly threw aside all apparatus, put in practice the principles which, as I had decided, ought to be sound, and in six months brought my foot into a condition never again to give serious trouble, soon becoming, and always remaining, practically as good as ever. This being so, I may, I think, be excused for once again insisting that the principles I have indicated are true, and the practice thereon founded important.

I am, Sir, yours faithfully,

Gloucester, September, 1886. T. S. ELLIS.

[2] "L'Anglaise marche les bras pendants, en appuyant sur les talons; la Française marche les bras pliés, en appuyant sur la pointe des pieds: c'est plus gracieux, mais moins commode."—*Les Filles de John Bull.*

THE EZRA HOSPITAL.—Sir Rivers Thompson last month laid the foundation-stone of a new hospital in Calcutta, to be called the Ezra Hospital, on a site near the present Medical College. The new institution is the gift of the widow of the late Mr. Ezra to the Jewish community, and is amply endowed with invested capital. It is specially intended for the reception of Jewish patients, and will, when completed, be under the control of the Principal of the Medical College.

THE REPORT OF THE PRESIDENT OF QUEEN'S COLLEGE, BELFAST.

(From our own Correspondent.)

THE annual report of the President of Queen's College, Belfast, for the session 1885-86 has just been printed. From it we learn that 131 students entered the College during the session, while the total number of students enrolled in each faculty was as follows: Arts, 205; Law, 12; Medicine, 244; School of Engineering, 16. Making allowance for 17 who attended in more than one department, the aggregate total of individual students was 460. It will be seen that the number of students in the Medical Faculty outnumbers the whole of those attending the other departments. Eight lady students attended classes in the Arts division, and the President expresses the hope that such changes may be made in the statutes as will open to students of either sex all scholarships, exhibitions, &c., in the Faculty of Arts, as is the law in the Royal University. The President urges very strongly the need of enlarged buildings and laboratories. The professors of chemistry, physics, natural history, anatomy, and physiology still complain of want of sufficient accommodation. Last year a small addition was made to the chemical laboratory; but even now there is not room for one-half the students in attendance; as a consequence the class has to be divided, and the professor has to repeat his lectures and demonstrations not unfrequently two or three times in the day. The progress of students is also seriously interfered with, for the laboratory should be open to them for practical work at all hours. In the departments of practical physiology and histology the laboratories, as the President reports, are much too small, and he hopes that an urgent application made to the Board of Works by Professor Redfern for some alterations which would secure additional space may be successful, and that before the commencement of next session the alterations he asks for may be made. Dr. Cunningham (the Professor of Natural History) has found it necessary to open a class in practical biology, but there is no room in the present building for a laboratory. Two rooms connected with the materia medica class-room were used, but they were unsuitable and much too small. A temporary arrangement has now been made by which the anatomical dissecting-room can be utilised for the purpose, as the class in practical biology does not open till after the close of the regular medical session. The total amount required for all these improvements is small, the estimate of the architect of the Board of Works, who prepared plans, being under £8000. It is to be hoped that the Government will see their way to grant this small sum. The great bulk of the students have entered the Royal University of Ireland, but it seems a hardship that it is necessary for from 300 to 400 young men to travel year after year to Dublin, thus entailing large additional expense, owing to the fact that the higher and all the honour examinations take place in Dublin; but, notwithstanding the difficulties with which they have to contend, the success of Queen's College students of Belfast at University examinations during the past year has been unprecedented. The President refers to the fact that at the opening of the summer session a Volunteer ambulance corps was organised by the medical students, and the College Council cordially approved of the movement and voted £50 towards the purchase of ambulance tents and stretchers. About 120 were enrolled, and they have for more than two months been regularly trained by a military instructor. Further, through the kindness of the military authorities, the corps accompanied the troops and practised ambulance work on field days.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NEWCASTLE JUBILEE EXHIBITION.

IT may not be known to some of your readers that we are about to have an exhibition of mining engineering and of the various industries in Newcastle. It will be on a very extensive scale, and it is proposed to have the opening on May 24th, 1887—it is to be hoped, under Royal auspices. Some idea of its extent may be gained from the statement

Digitized by Google

that already 30,000 superficial feet of floor-space have been applied for. The contract for the building has also been let to an eminent contractor, and it is to be proceeded with at once. Under the head of "sanitary appliances," our active city medical officer of health, Mr. H. E. Armstrong, reported that the committee for this department had been divided into nine subsections to carry out the different plans; and that, so far as they had gone, they had done their work well. Models of hospitals will be a feature of this section, and the Tyne Port Sanitary Authority and the Newcastle Corporation had given Mr. Armstrong authority to provide models of the hospitals recently built by them; and it was fully expected that models of other hospitals in various parts of the country would be sent in, so that altogether the sanitary exhibits promise to be a leading feature.

AN ALTAR TO ÆSCULAPIUS AT SOUTH SHIELDS.

Mr. Gowans of South Shields, in his late address to the Northern Branch of the British Medical Association, refers to the interesting discovery of a Roman altar at South Shields, which is now to be seen in the public Library Museum there. It is believed to be older than any of the inscribed stones which have yet been discovered in South Shields, and bears the following inscription:—"D. ESCVLAP. P. VIBOLEIVS. SECVNDVS. ARAM. D.D.," which may be translated—"To the God Æsculapius, Publius Viboleius Secundus gave [this] altar as a gift." Mr. Gowans, in his address, very effectively turns this discovery to good account for South Shields—which is proverbially healthy, and owing to the public spirit of its inhabitants is growing in deserved repute as a health-resort—by remarking as to health visitors, "Already large numbers arrive, induced by the excellence and safety of the beach for bathing and the cheapness of living, &c. So history repeats itself, for as two thousand years ago pilgrims repaired hither to seek health at a shrine dedicated to Æsculapius, in a like manner they are arriving at the present day seeking similar benefits."

DEATH OF MR. T. J. TURNBULL, SURGEON, J.P., NORTH SHIELDS.

I regret to announce the death, on the 16th inst., of Mr. T. J. Turnbull, M.R.C.S., who was well known as an active practitioner in North Shields. Mr. Turnbull was a pupil of the late Sir John Fife, and was in his fifty-sixth year. Mr. Turnbull had a severe illness about two years ago, from which it was hoped he had fully recovered, but he never fully regained his former condition. In politics Mr. Turnbull was a Liberal, but he took little part in public affairs except as a member of the School Board. Mr. Turnbull's father was the proprietor, and I believe the originator, of the well-known "Turnbull's Shipping Register." His funeral took place on Saturday last, and his remains were followed to the grave by a large number of professional friends and mourning patients. He has left a widow and one child.

TESTIMONIAL TO MR. GAMMAGE OF SUNDERLAND.

Mr. Gammage, a highly esteemed general practitioner at Sunderland, having been compelled to relinquish practice in consequence of ill-health and increasing infirmity, it has been decided to present him with a testimonial of esteem. Influential committees of practitioners have been formed to further the object in Sunderland and Newcastle, and I hope to be able at a future time to record their success.

Newcastle-on-Tyne, Sept. 20th.

EDINBURGH.

(From our own Correspondent.)

DIRECT REPRESENTATION ON THE MEDICAL COUNCIL.

THE near approach of the election of a Direct Representative of the Profession in Scotland to the General Medical Council has awakened a good deal of interest in different localities throughout the country, and a number of candidates for the post are now in the field. This interest, chiefly manifested as it is in the foci of thickest population and of most obvious medical activity, illustrates two of the special characteristics of this country, true also to a great extent of England, and in both countries interfering seriously with an easy solution of the important question who the direct representative shall be. The first point is the entirely unorganised condition of the medical profession, making it well-nigh impossible for it to realise and to profit by its enfranchisement; the second is an outcome of the restricted intercommunication between different parts of the country that till lately obtained, and that has given rise to a system of isolated interests which cannot but make its influence felt here, as in so many other relations where the idea of clanship is still a most potent factor. Thus one finds, on looking at the list of Scottish candidates, the north, the east, and the west each represented by an able champion, any one of whom might well represent the medical interests of the whole country. Dr. Bruce of Dingwall, an Aberdeen graduate, and widely known and respected throughout the north, will doubtless secure numerous suffrages in the region of which Aberdeen is the medical metropolis. Coming south to Dundee, one finds Dr. Robert Sinclair in the field, the energetic secretary of the Forfarshire Medical Association, and, in the mind of that part of the profession which occupies the eastern provinces, pre-eminently the best man for the post. Passing westward to Glasgow, one comes to another still more numerous constituency, no less isolated in its views than the two preceding, and here enthusiastic efforts are in progress for the election of Dr. James Morton, well known for his contributions to operative and conservative surgery. If my view be correct, votes will be cast largely in reference to latitude and longitude. As yet no additional candidate has publicly entered into the contest, so that Edinburgh interests have not yet been specifically touched upon. It has, however, been mooted that Sir Douglas Maclagan might appear as a candidate who would prove acceptable to a very wide constituency, but as yet no such step has been taken. Nor is it likely that it will be, since a contested election can scarcely prove an attraction to one so long engaged in arduous effort, and so laden already with the weight of universal admiration and well-merited honours. But apart from this, the particular interests which Sir Douglas Maclagan could not but represent, were he chosen for the post, are provided with special means of representation under the clauses of the new Medical Act.

Edinburgh, Sept. 21st.

IRELAND.

(From our own Correspondent.)

DIRECT REPRESENTATION IN IRELAND.

THERE is little to chronicle in respect to the contest which will take place next November for a member to represent the medical practitioners of Ireland in the General Medical Council. There are some five candidates named as likely to come forward. It has been pointed out that it would be advisable that Dr. Jacob should intimate his intention of resigning the secretaryship of the Council of the Royal College of Surgeons if he be successful, but this he has refused to do, although it is very improbable that the Council would permit him to hold the two offices simultaneously. So far no committee, to my knowledge, has been appointed, as in the sister countries, to promote the election of the various candidates, nor is it at all probable that one will be constituted.

THE EPIDEMIC OF FEVER AT HARE ISLAND.

A second death has occurred—that of a nursing sister, who contracted typhus fever while in the discharge of her duties, and was admitted to Skibbereen Fever Hospital, where she died. The water-supply of the island, as was expected, is not all that can be desired, and last week, at a meeting of the Skibbereen guardians, a communication was received from an analyst in Cork, stating that two samples of water from Hare Island were found to be polluted and thoroughly unfit for use.

THE LATE SURGEON G. O'GRADY, A.M.D.

Last week the remains of Surgeon Goodwin O'Grady, Army Medical Department, were interred with full military honours in the military cemetery, Cork. The deceased officer was thirty-two years of age, and was the son of the late rector of Magourney. The firing party was comprised of 100 men of the Argyleshire Highlanders, General Stevenson commanding the Cork district; the principal members of the head-quarters' staff and other officers stationed in the garrison forming a portion of the funeral *cortège*.

ATTACK ON DR. BUTLER, OF LIMERICK WORKHOUSE.

An attempt was made recently to stab Dr. Butler, one of the resident physicians attached to this workhouse, and last week his assailant was sentenced to two months' imprisonment.

An address has been presented to Dr. Jameson Dwyer, late resident physician of the Mullingar Asylum, on his promotion to the post of resident medical superintendent of the Cork District Lunatic Asylum.

Dublin, Sept. 21st.

MEDICAL NOTES IN PARLIAMENT.

Richmond Lunatic Asylum (Ireland).

In the House of Commons on the 16th inst., in answer to Mr. Corbet, Sir M. Hicks-Beach stated that there are in the Richmond Lunatic Asylum 1094 patients, of whom 907 are Catholics. There are five medical officers, one of whom is a Catholic, but the only appointment for which the Government is directly responsible is that of the resident medical superintendent.

The Medical Staff of the Post Office.

On the 18th inst. Mr. Pickersgill, in a lengthy speech, called attention to the conduct of the medical staff of the Post Office, which he alleged to be oppressive so far as the *employés* were concerned, and injurious to the public interests. Mr. Isaacson supported Mr. Pickersgill, and said that a spirit of dissatisfaction existed with regard to the manner in which the department in question is conducted. Mr. Raikes replied, and completely exonerated the officials from the charges of neglect which had been brought against them.

The Troops in Egypt.

On the 20th inst. Mr. W. H. Smith, replying to Mr. Buxton, stated that there was at the present time no abnormal sickness among the troops at Assouan. The number of troops in Egypt had, however, recently been considerably reduced, and it was hoped that it would be possible to effect a still further reduction very shortly.

Water Companies and the Public.

On the 23rd inst., in reply to Mr. Pickersgill, Mr. Ritchie stated that the report for the past year of Mr. F. M. Corner, medical officer to the Poplar Board of Works, respecting the stoppage of the water-supply to houses for non-payment of the rate, calls attention to a condition of affairs that urgently demanded a remedy. The Government had no power over the water companies, but he earnestly hoped that they would take care that the powers which they possessed by law were not exercised in such a manner as would be detrimental to the community and extremely hard upon the tenant. In his opinion, it was absolutely necessary that the law relating to the cutting off of water should be amended.

Metropolitan Asylums Board.

In reply to Mr. Rowlands, Mr. Ritchie stated that the Local Government Board had recently increased the number of elected members of the Metropolitan Asylums Board by nine. The change had been made in consequence of the great alterations which had occurred in the population and ratable value of the unions and parishes in the metropolis since the number of members was fixed in 1871, and the large additional duties which the managers had now to undertake as compared with those which devolved on them at that time. The present number of elected managers was 54, and of nominated managers 15.

The Belfast Hospital.

In reply to Mr. Sexton, Sir M. Hicks-Beach said that a deputation had waited upon the Lord Chancellor to urge the claim of the Belfast Hospital to a grant in consequence of the great access of patients during the late riots, but they did not give him information upon the precise points which he required. He could not at present recommend a grant for the ordinary service of the hospital, and although the number of patients treated on this particular occasion was numerous, it formed a very small proportion of the number of patients treated during the year. He fancied there was some arrangement under which payment was already made in regard to members of the constabulary and soldiers treated, but he would undertake to look into the matter from that point of view, and if there should be sufficient ground he certainly should recommend a grant for the services rendered.

Obituary.

JOSEPH SAMPSON GAMGEE, F.R.S. ED.

We regret to announce the death of this well-known surgeon, which took place at his residence in Birmingham on Saturday, the 18th inst. Five years ago Mr. Gamgee was laid by for some weeks with a serious attack of hæmaturia, which evidently left its mark upon his kidneys and his general health. He regained, however, a fair amount of strength, and was enabled to follow his ordinary avocations with apparently his usual vigour. Three weeks ago, while walking quickly along one of the streets at Dartmouth he slipped, and, falling, injured his hip. Though suffering acute pain, he was unwilling to admit that there was any grave damage, and under the careful superintendence of his two sons, he was brought home in a litter and placed in bed. Here for a fortnight he saw his patients and dictated his correspondence, at times even getting from his bed into an easy chair. At the end of this time, not being satisfied with his condition, he consented to have ether administered, and a more thorough examination made of his injury, the conclusion arrived at being that there was a fracture of the upper end of the right femur. Three days afterwards he became sick; the next day he vomited blood and had abdominal distension, and on the following day suppression of urine, death ensuing in the evening, with his intelligence unimpaired to almost the last moment.

Mr. Gamgee was born at Florence in 1828, and was consequently in his fifty-ninth year. The son of an eminent veterinary surgeon (still living in Edinburgh), at first he was destined for the same calling, but subsequently he became a student at University College and entered the medical profession, studying afterwards at Paris, Pavia, and Florence. During this course of education he gained that mastery of languages which in after-life adorned his career, and made him a facile exponent both of the writings and teachings of continental authors, especially French and Italian. This art also led to his appointment as corresponding member of several foreign learned societies, and gave him the opportunity of supplying abundant contributions to the literature of his profession from many sources. Exhibiting in his student days the promise of an exceptional and brilliant career, he became surgeon to the Queen's Hospital, Birmingham, in 1857, a post which he held until his illness in 1881, when he was appointed consulting surgeon.

Into the conduct of his duties at the Queen's Hospital he threw himself with intense zeal and activity, and in both the professional and administrative work laboured unceasingly to promote the reputation and welfare of the institution. The extension of the hospital and the origin of the Hospital Saturday collections were mainly owing to his influence and exertions, and in the details of these movements he gave valuable assistance and incessant labour. While president of the Medical Institute, by his unwearying devotion, he added largely to the library and the fund connected with it; and as president of the Birmingham Branch and Midland Medical Society he worked ardently in their respective interests. He lately pleaded eloquently for the members of the College of Surgeons in their efforts to obtain direct representation on the Council of the College, and always sought to impress the right of direct representation of the profession in various ways. As an author, his works on the Treatment of Fractures and on the Treatment of Wounds illustrate the clearness and precision of his writing. Various monographs—"Harvey and Cæsalpinus," "Vivisection and Human Surgery," "The Hospital Saturday Movement," &c.—testify to his literary power and ability. As a strenuous advocate of treating wounds by dry and infrequent dressing, rest and immobility, his teaching was expressed in a form which exhibits a wide knowledge of surgical literature and his complete mastery of fine and graceful writing. In addition to his being a prolific writer on surgical and professional subjects, Mr. Gamgee was an exceptionally eloquent and facile speaker. His presence at meetings and medical societies always commanded interest and received attention. Fluent and profuse in his command of language, dramatic in his manner of expression, he elaborated argument and poured forth criticism in a manner which carried his audience with him

Digitized by Google

and evoked admiration. Enthusiastic to a degree in all he undertook, he championed his cause with a fervour which was refreshing and invigorating, while his power of observation and comprehensiveness gave him a grasp of his subject which almost compelled conviction.

Mr. Gamgee, though actuated always by a high public spirit, and in friendly relations with every leading man of the town, never took any active part in public affairs outside his profession, but was content to give his advice and counsel freely in all matters having a professional bearing. His intimate acquaintance with the working of the medical charities rendered his opinion valuable and sought after.

As a man of varied talents and extensive literary knowledge, as an eminent writer on surgical and allied topics, as a loyal citizen and generous friend, his absence will be conspicuous and difficult to fill. Mr. Gamgee leaves a widow and four children to mourn their loss.

We publish the following from a correspondent:—

Late on Saturday night, 18th inst., died J. Sampson Gamgee, passing away calmly, peacefully, and painlessly, after a very short illness. Let others who are qualified to do so speak of his professional career and attainments; I, who knew him rather intimately, ask a small space in your paper to speak of him as I knew him, at home and as a friend. He was, in every sense of the word a model, and most devoted husband and father; but here the child was only the father of the man, as our departed friend was a most devoted son to his parents. Where he made friendships they were deep and sincere attachments, and his repeated kind actions, not only in great but in little matters, will ever be held in grateful memory by those who enjoyed the rare privilege of his intimate acquaintance. No trouble was too great for him when he wanted to do a kind action. His wonderful gifts of language, feminine delicacy of touch, and perfect tact were such as fall to the lot of few men to possess. He was a man of deep and true religious feeling, which was intensified during and since the serious illness under which he suffered some five years ago. Among his favourite pieces of sacred poetry may be especially mentioned Psalm xxiii., and "Lead, kindly light, amid the encircling gloom." His genuine religion found expression in such acts of kindness and self-denial as could have no other source. His premature decease, in the ripe autumn-time of his splendid talents and matured experience, leaves a void in his circle of relatives and friends which will be bitterly felt and never again filled. It is more than probable that his disease may have been hastened considerably by the immense amount of brain and body work which he crowded into his useful life. He was always an enthusiastic student of his profession, and could not do either his lay or professional work by halves, on account of his innate earnestness of purpose. In conclusion, a very correct summing-up of his nature may be found in the words of one of his favourite authors: "Take him for all in all, we ne'er shall look upon his like again."

Medical News.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on Thursday, the 16th inst.:—

Doyle, Henry Martin, Melbourne, Victoria, Australia.
Moxon, Alban Henry, King-street, Great Yarmouth.
Walker, Fredk. Wm., Aldborough, near Darlington, Yorkshire.
White, Cresswell Fitzhert, Chippenham, Wiltshire.

The following gentlemen passed the Preliminary Examination in Arts on the 10th and 11th inst.:—

FIRST CLASS.—H. E. Cooper, C. B. Dale, A. C. Gask, W. F. E. Milton.

SECOND CLASS.—J. C. Bowden, B. H. Carpenter, L. V. Cooper, C. A. Coventon, T. S. Davies, F. Deas, J. M. Duncan, H. F. Haland, E. Flint, B. B. Ghose, S. F. St. D. Green, W. R. Grove, A. A. Hewer, W. C. Hinde, P. S. Kesteven, H. Meyrick-Jones, J. J. Mooney, F. H. O'Donel, F. E. Oram, W. C. Orme, A. W. Perry, E. W. Prentice, R. H. Reynolds, H. Sisson, L. G. E. Snead, S. L. J. Steggall, S. W. Sweetnam, J. G. Turner, R. S. Whitford, F. E. Withers, W. E. Wyborn.

ELEMENTARY MECHANICS ALONE.—C. W. Allen, L. S. Baines, W. Birkett, F. L. Charters, A. T. Collett, C. W. Crasweller, F. J. A. Dalton, C. T. W. Hirsch, H. A. Jullus, F. W. Kerkey, A. King, F. C. Lewis, H. W. Lyle, D. T. Maddock, N. Marder, M. C. O'Brien, F. O'Byrne, G. E. Page, H. L. Powys, G. F. C. Prance, H. Reeks, J. J. D. Richardson, F. C. Rundle, G. J. Rutherford, F. Scorer, J. H. B. Simons, M. K. Thomas, G. M. Y. Whittingham, C. H. Willis, J. J. Winn, E. Yonge.

A CONGRESS of Russian alienists will meet in October.

THE Winter Session of the Charterhouse Science and Art Schools will commence on Oct. 2nd.

A CONFERENCE of those interested in the care of idiots has just been held in Frankfort-on-the-Maine.

THE GERMAN MILITARY MEDICAL JOURNAL.—Staff Surgeon Dr. Lenhartz has been appointed editor of this Journal in place of Dr. Bruberger, recently deceased.

AT the Hammersmith Police-court, on the 21st inst., a Fulham butcher was fined £40 for exposing for sale joints of meat which were unfit for human food.

ON the 18th inst. a very successful demonstration was held in Plaistow on behalf of the proposed hospital for West Ham.

A HOSPITAL SUNDAY was inaugurated at Henley on the 11th inst., the proceeds of the collections being devoted to the Royal Berks Hospital.

THE GROCERS' COMPANY SCHOLARSHIPS.—Dr. G. Sims Woodhead, of Edinburgh, has been awarded one of the Research Scholarships offered by the Grocers' Company.

ALEXANDER KRAPOTKIN, a Russian biologist, physicist and astronomer, who was banished to Siberia in 1874, has recently shot himself in Tomsk.

THE students attending the Newcastle-on-Tyne Throat and Ear Hospital, the medical staff, and other friends have presented the Senior Surgeon, Richard Ellis, Esq., F.R.C.S. Edin., with a handsome silver claret-jug and salver, as a token of their esteem.

ENTERIC FEVER AT HINCKLY.—A serious outbreak of enteric fever is reported to have broken out at Hinckly, in Leicestershire, where a large number of people are suffering from the disease, and some have died. No fewer than sixty cases have been attended by one medical gentleman.

THE POLICE AND AMBULANCE WORK.—Arrangements have been made for the instruction of the Singapore Police Force by the local centre of the St. John Ambulance Association, the Government undertaking to defray two-thirds of the cost, and the centre the remaining third. Many Chinese are life or annual subscribers to this centre.

A WOMAN who recently applied for admission to the Richmond Workhouse, on being asked as usual to enter the bath, refused to do so, stating that she had not washed her body for nine years. On being informed that the rule could not be relaxed, the applicant decided to leave the house rather than submit.

SEASIDE CONVALESCENT HOME FOR WORKING-MEN.—At a meeting of the committee and friends of this institution on the 18th inst., it was stated that the Home has, since its establishment three years ago, afforded rest and shelter to over 1000 convalescents. For some months past it has been impossible to find room for the number of applicants, and the hope was expressed that at an early date it may be possible to considerably increase the accommodation afforded.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—At the half-yearly meeting of the Governors of the Wolverhampton and Staffordshire General Hospital, held in the Medical Institute, Cleveland-road, on Tuesday, September 14th, the chairman, after the conclusion of the formal business of the meeting, on behalf of the subscribers, presented to Dr. Millington his portrait, and to Mrs. Millington a silver salver and a silver tea and coffee service. Dr. Millington, who is now one of the consulting physicians, had been honorary physician for thirty-two years, and his portrait will be placed in the board-room of the hospital.

PROPOSED IMPERIAL INSTITUTE.—In a letter to the Lord Mayor, the Prince of Wales has suggested, as a commemoration of the jubilee of Her Majesty's reign, the establishment of an institute which will represent the Arts, Manufactures, and Commerce of the Queen's Colonial and Indian Empire. The Lord Mayor has expressed his approval of the scheme, and a fund is to be opened at the Mansion House in furtherance of the project. It is anticipated that arrangements may be made whereby the more important collections now being exhibited at the Indian and Colonial Exhibition will be placed at the disposal of the proposed institution.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ADAMSON, JAMES, M.D.Glas., L.R.C.S.Ed., has been appointed Medical Officer for the Hetton-le-Hole District of the Houghton-le-Spring Union.

ALLNUTT, JOHN, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Seventh District of the Blything Union.

BERRY, EDMUND, L.K.Q.C.P.I., L.F.P.S.Glas., has been appointed Medical Officer for the Leyland District of the Chorley Union.

COTTERELL, EDWARD, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Stoke Lyne District of the Bicester Union.

CROSSE, WILLIAM HENRY, M.R.C.S., L.F.P.S.G., L.S.A., has been appointed Surgeon to the National African Company.

DIXON, GEORGE F., L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Tyldesley District of the Leigh Union.

DIXON, WALTER, M.B., C.M.Ed., has been appointed Medical Officer for the Second Division of the Houghton District of the Dover Union.

DUNDAS, MORDAUNT G., M.R.C.S., L.S.A., has been appointed Medical Officer for the Fransham District of the Mitford and Launditch Union.

FOWLER, CHARLES O., L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Second District of the Croydon Union.

WARWICK, F. J., M.B.Camb., M.R.C.S., has been appointed Medical Officer for the Shepperton District of the Staines Union.

WARWICK, PERCY, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Workhouse of the Blything Union.

Births, Marriages, and Deaths.

BIRTHS.

BARNES.—On the 19th ult., at St. George's, Bermuda, the wife of Surgeon H. J. Barnes, Army Medical Staff, of a son.

KIRKPATRICK.—On the 15th inst., at The Shrubbery, Canterbury, the wife of Hugh Cunningham Kirkpatrick, M.D., Surgeon Medical Staff, of a son.

LAWRIE.—On the 19th inst., at Greenhill, Weymouth, the wife of Macpherson Lawrie, M.D., of a daughter.

MARRIAGES.

CARTER—KELLY.—On the 15th inst., at the Parish Church, Rawdon, by the Rev. Reginald R. Kirby, Vicar of St. Matthew's, Chapel-Allerton, assisted by the Rev. T. Kelly, Vicar of Mapleton, Hull, uncle of the bride, and the Rev. Arthur Kelly, Curate of Wensley, brother of the bride, D'Arcy Bainbridge Carter, M.R.C.S., of Shipley, son of J. B. Carter, M.R.C.S., of Elm House, Chapel-Allerton, to Amy Georgiana, fourth daughter of the late Rev. W. Kelly, Vicar of Shipley.

DUNLOP—BEGBIE.—On the 8th July, at Loudoun, Dalby, Queensland, by the Rev. Dr. Nelson, grand-uncle of the bride, William Watson Dunlop, second son of John Dunlop, M.D., Glasgow, to Francis Dunlop, eldest daughter of Hugh Begbie, late of Edinburgh and Glasgow.

JAMES—DAVIS.—On the 15th inst., at the Parish Church, Killeagh, co. Cork, Charles Edward James, M.B., to Rebecca, eldest daughter of the late William Davis, Esq., of Killeagh House, Killeagh, co. Cork.

KENDALL—GATLEY.—On the 22nd inst., at St. Michael's, Folkestone, by the Rev. E. Husband, George Kendall, M.R.C.S., L.R.C.P.Lond., of Battle, to Ada Gatley, third daughter of the late James Clark Gatley, of Truro, Cornwall.

ORR—IHLER.—On the 16th inst., at St. James's Church, Belfast, Andrew Aylmer Orr, M.A., M.B.Oxon, to Matilda Amelia, youngest daughter of the late George James Ihler, of Rockfield, Gateacre, Liverpool.

SCOUGAL—HIRST.—On the 16th inst., at the Parish Church, New Mill, Yorks., by the Rev. H. J. Holmes, M.A., Vicar, Edward Fowler Scougal, M.B., C.M., Huddersfield, to Clara, younger daughter of the late Charles Hirst, of Birdsedge.

STEELL—DUNLOP.—On the 22nd inst., at St. Paul's, Withington, Manchester, by the Rev. Canon Lloyd, M.A., Vicar of Leesfield, Graham Steell, M.D., youngest son of Sir John Steell, Edinburgh, to Agnes Dunlop, eldest daughter of the late Rev. Thomas M'Kie Erskine, Renfrewshire.

DEATHS.

CLARKE.—On the 9th inst., at Bank House, Morley, near Leeds, Grace Marion, wife of J. C. Clarke, M.R.C.S., aged 46.

GAMGEE.—On the 18th inst., at his residence, Broad-street, Birmingham, after a short illness, Joseph Sampson Gamgee, M.R.C.S., F.R.S.B., in his 59th year.

HAYLE.—On the 17th inst., at The Crescent, Rochdale, Thomas Hayle, M.D., in his 78th year.

STEPHEN.—On the 11th inst., at Carlsbad, of cholehæmia, William H. G. Stephen, M.B., C.M.Ed., M.R.C.S.Lond., youngest son of the late William Stephen, Inchbroom, Morayshire, aged 24.

WHISH.—On the 12th inst., at Boulogne-sur-Mer, France, Martin Samuel Whish, M.R.C.S., L.S.A., aged 27.

WOODMAN.—On the 15th inst., at Ramsgate, Samuel Woodman, J.P., M.D., F.R.C.S., aged 45.

WOODS.—On the 15th inst., Everard Woods, L.K.Q.C.P. and L.M.I., of the Great House, Leyton, Essex, aged 26.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

PRISON SURGEONS.

IN reply to correspondents who ask for information as to the mode in which appointments are obtained to the surgeoncy of prisons, we may say that application should be made to the Directors or Commissioners of Prisons, and the appointments are in the hands of the chairman, Sir Edmund Du Cane.

Belvedere Ivy.—The ordinary medical attendant should be consulted on the matter. We do not prescribe.

MEDICAL CLUBS AND FRIENDLY SOCIETIES.

To the Editor of THE LANCET.

SIR,—Industrial assurance companies and friendly societies are finding it a difficult matter to keep their business together now-a-days, and they have hit on a new expedient for securing and retaining members. Two companies to my knowledge are at present trying the experiment, which is as follows:—They are forming medical clubs in connexion with the insurance business, and offering the appointment of medical officer to the medical gentlemen who have a large club connexion in the several districts. The name of an insurance company sounds profitable, and in many cases the appointment is accepted—with what result? The doctor finds many of his private patients enticed into the new club (every member of which must, as a *sine qua non*, also become a member of the insurance company), and many of his club members transferred on the same conditions to the new club, and perhaps lost. In fact, the doctor is made an unconscious lever with which to raise insurance business.

I hope medical men will accept this warning.

I am, Sir, yours faithfully,

September, 1886. NOVUS HOMO.

"MASSACRE OF THE INNOCENTS."

To the Editor of THE LANCET.

SIR,—With reference to an annotation in your last issue (p. 547), headed as above, the only wonder to me is that more massacres are not brought to light, considering how easily the public obtain poison. At the commencement of the present month a mother brought one out of six of her children, all suffering from ringworm, to me. On my inquiry as to what she had done for it, she said she had painted it night and morning with a solution of corrosive sublimate, six grains to the ounce, which a chemist she knew had supplied her with without signing her name. This is only one of several cases that have been under my notice recently where deadly poisons had been used, where there is little doubt much simpler remedies would have availed.

I am, Sir, yours obediently,

Sept. 21st, 1886. PHYSICIAN.

AMBIGUOUS CHARITY.

THE other day a grand ball was given at the Hôtel Schweizerhof at Lucerne in aid of the sufferers from cholera in Italy. Several thousand francs, the proceeds of the entertainment, were handed over to the Italian Relief Committee, more, it is said, to the advantage of Switzerland than of Italy. In the words of an "Indignant Italian," the "impression is thus made general throughout Europe that Italy is sore stricken with cholera, and travellers are afraid to cross the Swiss frontier, to the serious detriment of Italian hotel-keepers and tradesmen, and to the corresponding gain of the astute Switzers, while the subalpine lakes from Lago Maggiore to Lago di Garda were never healthier or more attractive."

Nous Verrons.—While there is undoubtedly some hardship involved in the regulation to which our correspondent refers, it is very doubtful whether that could be obviated without inflicting a much greater injustice. The conditions of service of the two classes referred to are so essentially different as to vitiate any comparison of the regulations applicable to them.

Mr. H. M. Morgan (Lichfield) is thanked.

TONSILLITIS AND ITS RELATION TO SCARLATINA AND DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—Allow me to thank Dr. F. P. Atkinson for his comments upon my article on the above subject in your issue of July 31st. It is a subject in which, as is well known, he has taken especial interest.

Without attempting to discuss the questions involved, may I be allowed to add a few words by way of removing some misconceptions of my position? I do not assert anything as to the causes or nature of inflammations of the tonsils in general. There may be, and are, many different forms. I have merely singled out and described certain common forms of tonsillitis which have, as I think, a relation to scarlatina and diphtheria. Far from saying, then, that "tonsillitis is always the result of some scarlatinal or diphtheritic poison," my suggestion is that the forms in question are caused by a poison of the same class as those of scarlatina and diphtheria, but differing by its inability to infect the system. It is a question of terms whether you call such a poison "specific" or not. I should not, in strictness, call it so. A specific poison is that which produces a "species" of disease; and this dignity I would reserve to a disease which infects the system, running a definite course, and being communicable to a fresh subject. Some infectious sore-throats ("false diphtheria") are, indeed, communicable under some conditions, but they seem soon to lose this power: they correspond to a "specialised" disease, as the term was used by Mr. Hutchinson in his recent Lettsomian Lectures. That the tonsils, like other lymphatic organs, are liable to chronic enlargement in strumous constitutions is a fact of common observation, but it is in no way incompatible with the theory stated. Peyer's patches are often found enlarged at the autopsies of weakly children, but the inflammation of those glands which occurs in enteric fever is surely none the less due to a specific poison. That in their general pathology the tonsils are to be associated with the other lymphatic glands I fully believe. But it is a very remarkable circumstance that certain of these glands should be planted on the free surface of the alimentary canal, the tonsils above, Peyer's and the solitary glands below, and that it is these glands, thus apparently exposed to infection, which are the seat of the specific lesions of scarlatina, diphtheria, and enteric fever.

I am, Sir, yours truly,

Finsbury-circus, Sept. 13th, 1886. R. HINGSTON FOX.

VACCINATION IN WEST AFRICA.

To the Editor of THE LANCET.

SIR,—Your remarks about the faith of the natives of East Africa in vaccination are equally applicable to West Africa—at least, so far as the Gold Coast is concerned. On examining some 150 men of the Hausa constabulary, with a view to vaccinating them, I found that at least one-third of them had been vaccinated "in our country," which comprises a large tract, including Sokoto, Dagomba, Salaga, and other places but little known to Europeans. On one occasion one of these native vaccinators brought me three of his children to vaccinate, and intended taking them immediately into the interior as "sources of lymph." He, however, declined my offer of a few tubes, on the ground that the people in the interior would deem it "white man's fetish." Along the coast, however, where the native comes into immediate contact with the white man, this prejudice does not exist.

I am, Sir, yours faithfully

C. H. EYLES,
Assistant Surgeon, Gold Coast Colony.

New Hampton, Sept. 18th, 1886.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—In your last issue there is reference to a *Dr.* Rugg, as issuing circulars of a highly objectionable nature. As the name is uncommon, therefore the more noticeable, allow me to say that neither I nor my son—a registered practitioner—has so far lost our self-respect as thus to dishonour the profession, and to bring our name into disrepute.

I am, Sir, your obedient servant,

Clapham-road, S.W., Sept. 20th, 1886. GEORGE PHILIP RUGG, M.D.

TERATOLOGY.

J. W. C. (Cork).—A more striking and, from the psychological point of view, more interesting monstrosity than the "two-headed nightingale," as the poor girl was called when exhibited in these islands some ten or twelve years ago, is described in the "Historia Rerum Scoticarum" of George Buchanan. In the reign of King James III. of Scotland there was born in that country, about the year 1466, a creature having the lower part of its body like that of a human being of the male sex, but from the umbilicus upwards having a double trunk, double head, double arms, each limb and organ in duplicate, and all quite normally developed. King James was much interested in this phenomenon, the more so as it showed much aptitude for education. He accordingly put it under suitable masters until, among other acquisitions, it became quite a proficient in music, for which it had all the taste of a born artist. It also learned to speak several languages, and as it had two wills or faculties of volition it would sometimes have a quarrel with itself, and argue the point in dispute *pro* and *con*. At other times, when both itselves were in agreement, it would discuss what was best for the common interest. There was this notable circumstance about it, moreover, that when the loins or the lower limbs—any part below the umbilicus, in fact—were hurt, both upper bodies were sensible of the pain. But if either body above the umbilicus were pinched or otherwise made to suffer one body only felt the lesion. The difference between the two was even more marked when death overtook one of the bodies. The survivor lived after the decease of its neighbour until decomposition began to show itself in the latter, and then it also gradually dwindled away. This took place in the administration of the Regent John, in the nonage of King James IV., about the year 1490, the monster having lived rather more than twenty-eight years. "Hac de re scribimus eo confidentius," says Buchanan, "quod adhuc supersunt homines honesti complures qui haec viderint." (On this phenomenon we write the more confidently as there are still alive a great many respectable individuals who actually saw what I have been describing.) Buchanan himself was born in 1506, and acted as tutor to King James VI. from 1565 till within a few months of his death in 1582. It was during the latter years of his life that he composed his great History of Scotland, in Latinity which was the envy of the Sorbonne.

Medicus.—The bromides seldom cause such symptoms; but the diseases for which they are prescribed are attended not unfrequently with vaso-motor symptoms.

F.R.C.S.—No special morbid appearances have been observed hitherto.

THE CLIMATE OF VENTNOR.

To the Editor of THE LANCET.

SIR,—Having read your able article in THE LANCET of August 28th relative to the climatic treatment of disease, I am anxious to remark on a passage in which you say: "Ventnor and Torquay are the mildest of the English resorts, but prove somewhat too relaxing for some constitutions." Now, although Ventnor and Torquay are almost identical as regards temperature, there is a vast difference in their relaxing influence, in consequence of the difference in the humidity of the atmosphere. I well remember an observation made many years ago by a physician who had resided at Torquay some years and then came to Ventnor, where he remained two years. In the course of conversation relative to the climatic influence of the two places he made the following striking observation—"that he existed at Torquay, while he lived at Ventnor." Ventnor as a place of residence on the south coast of England is far from relaxing, as the Undercliff, from its configuration, stands literally out at sea, the land trending sharply to the north at Bonchurch on the east, and the same at Blackgang on the west; and while it is comparatively warm in the winter, it is equally cool in the summer, from the constant influence of the sea-breeze.

My apology for addressing you is that I have taken interest in the meteorological observations of the Undercliff, and have continued the daily record first instituted by my brother, the late Dr. Martin, from 1839 to the present date, without the break of a single day, which can be said of very few places. The observations of the first forty years of the period were published by my nephew, Dr. Whitehead, on the occasion of the visit of the British Medical Association in 1881, of which I enclose a copy.

I have the honour to be, Sir, your obedient servant,

Ventnor, Aug. 30th, 1886. J. B. MARTIN, M.R.C.S.

"COCAINE IN GYNÆCOLOGICAL PRACTICE."

To the Editor of THE LANCET.

SIR,—Seeing an annotation in THE LANCET of Aug. 28th, p. 411, headed as above, could you spare me space to mention that I have seen cocaine used to painful vascular growths at the meatus with advantage by Dr. Oliver of Newcastle, and, I believe, others, with a certain amount of benefit, as a local anæsthetic. So that I believe Prof. Amann is by no means the first who has applied its use to gynæcology.

I am, Sir, yours truly,

Maidstone, Sept. 4th, 1886. PERCY T. ADAMS.

Digitized by Google

THE PROPOSED NATIONAL HOME FOR INVALIDS IN THE SOUTH.

To the Editor of THE LANCET.

SIR,—Two years ago, when I paid a visit to England for the purpose of visiting the hospitals there, my attention was in particular drawn to the Brompton Hospital for Consumption. Those who are suffering from that terrible disease and are excluded from other hospitals receive in this noble institution (supported chiefly by voluntary contributions) all the attention which skill and kindness can suggest. I next became acquainted with the hospital for consumptive patients at Ventnor (the originator of which, Dr. Arthur Hill Hassall, many have cause to bless), and here the good work for which it was erected is most successfully carried on. Whilst dwelling on what I had seen I was led to reflect how much greater good might be done if a similar institution could be established in a more suitable climate for patients of small means, or of none, suffering from consumption and other pulmonary diseases. I gave expression to my desire in a letter, inserted in *The Times* (Sept. 18th, 1884) and other English newspapers. The responses to this, containing promises of assistance and of subscriptions if the idea could be realised, were so encouraging that I have ever since been endeavouring to mature the plan by looking out for a suitable place for the erection of such a hospital.

As a physician with twelve years' practice on the Riviera, I have had under my care a very large number of patients suffering from consumption; and my experience has proved how very beneficial is the change of air, combined with proper diet, at the commencement of the disease. I therefore feel, as I am not aware that a like proposal has been previously made, that the time has arrived for me to appeal to the various Governments, clinical schools, benevolent societies, and all true philanthropists to aid me in rescuing from the terrible scourge of consumption the thousands who will otherwise, as hitherto, fall victims to it.

With regard to the following clauses—viz., (1) as to the necessity for such a home, (2) as to where it should be erected, (3) as to how it should be organised, (4) as to what sum should be collected before it can be started—a further pamphlet will shortly be published, a copy of which I will gladly send, free of cost, to all who may be interested in the undertaking. Any suggestions on the points mentioned will be heartily welcomed by

Yours obediently,

JOSEPH SCHNEER, M.D.

Alassio, Riviera di Ponente, Italy, September, 1886.

Justitia.—The Canadian qualifications are entitled to respect. But we do not consider that they fulfil the undertaking of the gentleman in this particular case. At present they are not registrable qualifications, and can only become so by the action of the Medical Council; and this is in the future.

HEREDITY IN THE LOWER ANIMALS.

To the Editor of THE LANCET.

SIR,—Possibly the following may be of sufficient interest to find a place in your columns.

A small, rough-coated cur bitch of mine had been taught to beg by turning round once or twice. At about fifteen months old she had a litter of six pups, and the only two of them which we know anything of turned round when begging before they were two months old. They did it when not served as soon as they wished, and it appeared quite spontaneously at first and indescribably curious, like a half-forgotten trick. I may say the mother was sent away from them too early to have taught them the trick—as soon, in fact, as they were fit to be left.

I am, Sir, yours obediently,

Kirkburton, Sept. 9th, 1886. GEORGE A. HAWKINS-AMBLER.

M.R.C.S., L.S.A.—In THE LANCET of April 8th, 1876, Dr. Ferrier recommended for the affection mentioned the use of a snuff composed as follows: Hydrochlorate of morphia, two grains; acacia powder, two drachms; trisnitrate of bismuth, six drachms; one quarter to a half to be used in the twenty-four hours. In a subsequent number Mr. Snagg, L.R.C.P., spoke highly of a combination of opium powder with compound tragacanth powder, in the proportion of one of the former to two of the latter, also to be employed as snuff.

"THE USE OF COCAINE IN CIRCUMCISION."

To the Editor of THE LANCET.

SIR,—I should think that every member of the profession is familiar with the fact that in the vast majority of cases of congenital phimosis the prepuce can be rendered retractable by dilatation; and a letter written for the purpose of pointing this out scarcely appears necessary. Amongst those who have been charged with the medical care of large numbers of young children there will probably be no doubt that a redundant prepuce, even if it can be retracted, is frequently a source of injury to its possessor.—I am, Sir, your obedient servant,

Inverness-terrace, Sept. 18th, 1886. GEOFFREY HETT.

Major St. H. de Entragues.—1. No.—2. We have no special knowledge of the place.—3. The book named is, so far as we are aware, the only one published on the subject.

M.B.—The waters are most valuable in scrofulous diseases.

PROF. CHARCOT "AT HOME."

DR. KRAUS, editor of the *Allgemeine Wiener Med. Zeitung*, writes to that journal (Sept. 14th), from Paris, a letter, in the course of which he describes a visit paid to Prof. Charcot:—

"My esteemed patron, Charcot, whose personal friendship I enjoy, had just returned from a holiday tour in Spain when I called upon him. Anyone entering the Palais Charcot, in the Boulevard St. Germain, fancies himself in an imperial residence; and, indeed, many a royal personage does not boast of such a palace as this. Charcot is admittedly not only the oracle of French physicians, but an authority upon medicine of the highest rank. We have so often touched upon the biography of this eminent scientist in our journal, and have told our readers so much of his insurpassable researches, that I need not now devote further words *ad majorem gloriam* of this eminent physician. Who is there among the ranks of medical practitioners who does not know Charcot and his imperishable work in the domain of cerebral disease, metallotherapy, &c.? I will not therefore to-day delineate him as the man of science, but as the Paris physician to whose tapestry-covered salon troops of patients make pilgrimage, and lay an obolus on the table, which groans under the weight of gold—from three to five to ten napoleons a consultation. How did I know all this if it were not that the pleasing testimony of this *aurea francogallica* practice lay piled up on the consultation table. To be sure, this modest, amiable, and highly humane French physician does not make a vain show of these offerings of esteem which his practice brings him; he simply has not time to place them under lock and ward, so rapidly does one patient press in after another. The consulting-room contains a magnificent library, which would be the envy of many a medical, Universität-Bibliothek; scarcely any important work of old and new medicine, home or foreign, is wanting. Charcot, the Nestor of French scientists, reads and speaks German, and my son and myself were delightedly surprised to see lying on the consultation table the *Allgemeine Wiener Med. Zeitung*, whilst on our entering he laughingly asked whether we knew that journal. Charcot gave us so much of his valuable time that we felt embarrassed, because we had seen what a crowd of patients still awaited his advice in the fairy-like salon. We were proud to secure a written souvenir from him, and a promise to send a paper to our journal. He asked after all his Vienna colleagues—Leidesdorf, Meynert, Benedikt, and proved how exceptionally conversant he is with Austrian and German medical literature."

Dr. Martin Oxley's note will appear in an early number.

AMBULANCE CLASS TEACHERS WANTED.

To the Editor of THE LANCET.

SIR,—I know of no class or profession more ready to do good than those whose work it is to cure or diminish the sufferings of mankind. I am sure, then, that the appeal I am about to make will meet with a generous response. Two years ago, at the annual gathering of the members of workmen's clubs affiliated to the Club and Institute Union, Lady Brassey earnestly invited them to form ambulance classes. In many of these clubs there is every disposition to follow this good advice, and I need not say what excellent results might be expected. The work in question would be doubly blessed—blessing those who learned to heal and the objects of their care. But the practical difficulty which has stood in the way is the necessary expense which attends all such undertakings. It is, of course, essential that the students should qualify themselves for certificates by passing the examinations organised by the St. John Ambulance Society. The small fee charged by that excellent Society for examinations many a club would be able to meet, and the Club Union will provide apparatus, books, &c. But very few of these institutions are able to provide the expense of a lecturer's fees; and this leads me to the object of my appeal. May I, then, ask any young medical practitioner not yet burdened by practice, or qualified medical student, willing to conduct one course of the required lectures at a workman's club in London to be so kind as to send his name and address to the Club Union Office. We desire to have a list of such generous friends, so that we may at any time provide any club which desires such services. Travelling expenses will, of course, be gladly paid by the club receiving this benefit. May I add, from a long experience, that those on whose behalf I write are always heartily grateful for any help of an educational kind. The lecturers will find intelligent and genial students; and I am quite sure that pleasant relations will be the result of such meetings between teachers and taught.

Any gentleman seeing this letter, and willing to act upon the suggestion which I have made, is requested to address: "Secretary, Workman's Club and Institute Union, 31, Southampton-street, Strand, London."

I am, Sir, yours faithfully,

September, 1886. HODGSON PRATT, President.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—In my letter on "THE LANCET and the late Dr. Wakley" the word "great," before "dramatist," should have been *Greek*. I intended to refer to the fact that in the majority of Greek plays the deaths of the characters take place out of the sight of the audience. Unlike Mr. Augustus Harris—I hope Mr. Harris will not consider the comparison invidious—the Greek playwright had great faith in the imagination of mankind.

I am, Sir, yours truly,

Glasgow, Sept. 18th, 1886. ROBERT MACPHERSON.

Medical Diary for the ensuing Week.

Monday, September 27.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2 P.M.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

Tuesday, September 28.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Wednesday, September 29.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Tuesdays and Fridays, 9.30 A.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.

Thursday, September 30.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M

Friday, October 1.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, October 2.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

Lectures
ON
DISEASES OF THE LACRYMAL APPARATUS.

Delivered at the Royal College of Surgeons.

BY HENRY POWER, F.R.C.S.

LECTURE II.—PART II.

THE canaliculi are occasionally obstructed by small olive-shaped concretions, which are termed "dacryoliths." They used to be regarded as calcareous masses, but have now been shown to be in great part composed of a fungus, and the history of the discovery is interesting. According to Goldzieher, Hirschler and Grube[1] first pointed out the occurrence of fungi in the concretions found in the canaliculi; but in the year 1855 A. v. Graefe[2] first described minutely some small concretions that he had observed in the canaliculi, and found that they consisted of closely interwoven filaments of a fungus which he then regarded as the mycelium of favus. In 1869 Prof. R. Foerster[3] reported a case in which the lower canaliculus was filled and dilated with a friable greasy-feeling mass, which had for years been the cause of persistent conjunctival inflammation of the eye. In this mass Waldeyer found the elements of fungi, which he considered to be identical with the leptothrix buccalis described by Robin and Lebert in the mouth, and which Leber and Rollenstein considered to be the principal agent in the production of caries of the teeth. Waldeyer noticed that the leptothrix filaments were surrounded by small round micrococcus and moving bacteria. Foerster had seen two analogous cases previously, but they had not been microscopically examined.[4] Immediately after the publication of Foerster's case, A. v. Graefe described seven more cases of such concrements in the lower canaliculi, in which Cohnheim and Leber also demonstrated the presence of, as they thought, leptothrix filaments similar to those of the mouth. The concrements were from 1·5 mm. to 3 mm. long, and about 1 mm. in diameter. These were sometimes like cheese, sometimes more sandy and friable; their colour yellowish white, though in Foerster's case the concretion was blackish externally.

On April 15th, 1874, Foerster removed a concretion, which he placed in the hands of Cohn. This mass was whitish, of tallowy consistence, easily broken down, and consisted essentially of delicate, colourless, parallel or closely interwoven filaments, which were either straight or arcuate, or here and there formed loops, or were closely and spirally wound in corkscrew fashion. These parts reminded Cohn of the corkscrew filaments of spirulina or spirochæta, from which, however, they were distinguished by their much greater irregularity. The filaments broke up into segments of various size, which were sometimes 50 mm. long or more. They did not dissolve in ammonia. These filaments were embedded and closely surrounded by finely granular micrococcus masses, which filled the spaces between the filaments. When a portion of the mass still under the cover-glass was submitted to the action of a gentle current of water, the filaments could be in great measure freed from the micrococcus, and it then became apparent that the filaments were extremely fine, that they were of equal thickness, that they ran for an uncertain distance straight and then formed irregular curves and spirals, and that they were also, though sparingly, branched. All these peculiarities, however, distinguish the filaments in the concretions of the canaliculi from those of the leptothrix buccalis, which are thicker, stiff, straight, distinctly segmented, and never branched, so that Cohn could not regard them as identical, and in none of the other instances was he able to recognise the characteristic parallel bristle-like filaments of leptothrix buccalis in the white masses of the canaliculi. He therefore arrived at the conclusion that it was a separate species, to which he gave the name of Streptothrix Foersteri. Cohn's culture experiments with it have given no results as to the exact relations of this organism; for whilst the external form of the filaments resembles certainly that of leptothrix, which is normally or pathologically present in other organs in man, their disposition to branch reminds one of the ordinary fungi. Cohn pointed out that some similarity exists between these concretions and the tartar of the teeth, which also consists largely of micrococcus with leptothrix filaments; and it was even suggested that the fungus might proceed from the transplantation of fungi from the mouth to the eye, rendered probable enough by the common practice of the poor to clean the eyelids of their children with saliva. Besides the filaments and the micrococcus, the lacrymal concrements contain actively moving bacteria, bacterium termo, as well as monads, which move in a springy way with the aid of a long flagellum. Cohn also observed small yeast-like cells and oidium-like gonidial chains, which perhaps were those described by Graefe as favus elements; even some fungate spores with long germ tubes were seen, but all these he was inclined to regard as secondary and subsequent formations. A somewhat different account, illustrated by figures, has been given recently by Cornil and Babes.[5] They recommend that the concretions should be teased out under water and stained with methyl violet. The filaments are then seen to be very fine, closely interlaced, undulating in their course like spiruli or spirochæta from which they only differ in being less regular. Sometimes they are segmented and micrococci found mingled with them. Goldzieher[6] has discovered cilia in the middle of the masses, and he believes that these parasites develop around a cilium which has entered the canaliculus. Babes found the thickness of the filaments to be constantly 0·2 mm. to 0·3 mm. throughout their whole length; the finest, however, appeared to have pointed extremities. Their substance is sometimes homogeneous, sometimes formed of rods, which colour strongly with many reagents, and are united by a less strongly colourable substance. The filaments may attain a length of 40 mm.; the smaller appear to result from the fracture of the longer ones. They are sinuous, or even run in corkscrew-like fashion, and appear to branch in a forked manner.[7] The symptoms produced by these little calculi are redness of the ocular conjunctiva, epiphora owing to occlusion of the duct, the presence of a small swelling in the course of the canaliculus, and dilatation of the punctum, from which a little mucus exudes. As a rule they cause but little irritation or pain, and do not attain a larger size than that of a lentil. The occurrence of these concretions seems to be more common than was at first supposed. Mooren saw no instance in upwards of 100,000 cases; but Mr. Higgens[8] has described a case occurring in the upper canaliculus, Haase[9] one in the lower; and Dr. Cornwell[10] has given the analysis by Mr. Curtis of what was probably a similar case, presenting the peculiarity of there being four calculi disposed like a necklace in the dilated canaliculus; one of these was found to consist of 28·3 parts of organic matter and 71·7 parts of calcium phosphate.

There can be little doubt that a certain proportion of cases of lacrymal obstruction is attributable to syphilis. The effects of that disease in causing tumefaction of the oral and nasal mucous membrane, its tendency to produce nodes, acute periostitis, and caries of the bones of the nose, thereby changing the direction, constricting or completely occluding the nasal duct, are circumstances that appear sufficiently likely to lead it to be generally mentioned in the etiology of the disease with the consideration of which we are now engaged. It is remarkable, however, that it is often omitted in the writings of modern authors, and one cause of this is probably to be looked for in the better treatment now adopted in the various forms of chancre, and to lend some colour to the opinions of those who attributed the frightful ulcers and diseases of the bones described, and often illustrated by our not very remote predecessors, to the indiscreet employment of mercury, and to the injudicious regimen to which patients were subjected when the subjects of syphilis. I have carefully examined the skulls of those affected with syphilis in the

museum of this College, but there are too few on which to found any statements. It can only be said that these parts do not appear to be specially liable to syphilitic disease, since they are quite free from disease in instances where the bones of the head are seriously affected. Excellent papers on this point have been published, in 1857 by Lagneau,[11] and in 1880 by M. Larebière.[12] This author found that obstruction of the lacrymal passages from syphilis occurred about seventeen times in 240 cases of lacrymal obstruction occurring in M. Galezowski's clinique in Paris, and he proceeds to consider the form of lacrymal disturbance that occurs in the primary, secondary, and later periods of the disease. To the first little attention has been paid, but since a chancre affecting any part of the margin of the lids causes much swelling and almost always more or less malposition of the puncta, it is clear that if it affect the region of the puncta it will occasion lacrymation by occluding the orifice of one or both, or by compressing the canaliculi. This condition will, of course, last only so long as the swelling lasts, and, as a rule, with the subsidence of this the canal again becomes pervious, but in some cases Larebière has observed that in the process of cicatrisation the punctum has become obliterated. It is hardly necessary to add that in such cases the canaliculus must be found and slit up, or some other proceeding for its restoration adopted. As regards the second period, the mucous membrane of the sac may either be primarily attacked, or it may be affected by contiguity and extension of disease from neighbouring parts. M. Larebière refers to the observations of various French authorities—as, for example, to M. Lancereaux—to show that "the affections which result from a modification of the mucous membrane of the sac and lacrymal passages usually make their appearance in the exanthematous period of the disease coincidently with erythema of the nasal and ocular mucous membranes, though they may also occur in the tertiary period." But it is extremely difficult to prove the existence of tumefaction in any given case. It might always be objected, in the absence of any ocular examination of the part, that a gumma was actually present in the sac, constituting the real cause of the obstruction. The point may, no doubt, be to a certain extent determined by the success or failure of efforts to pass a probe. If successful, the presence of a gumma is rendered more than doubtful; whilst failure, though possibly due to swelling of the membrane, might in the hands of an expert be attributed to the occlusion of the canal by some growth. In many instances, again, the mucous membrane of the lacrymal sac becomes affected by extension of disease of both the conjunctival and nasal mucous membranes. Here there is no difficulty in tracing the progress of the disease, and cases of lacrymal obstruction are not rare in infants presenting the usual manifestations of secondary syphilitic disease on the mucous membrane of the mouth and fauces. In regard to the tertiary period of syphilis many authors have drawn attention to the lacrymal affections which are then apt to occur, and we are indebted to M. Larebière for pointing out that, besides the periostitis and osseous tumours which have been commonly noted, gummata may occasionally be seen. These may occupy either the sac or the nasal duct, the symptoms being somewhat different in the two cases owing to the different anatomical disposition of the two parts. If the gumma develop in the sac, the progress of the disease is much slower than when it is situated in the nasal duct, for the yielding nature of the antero-external parietes of the sac permits considerable extension to take place without material interference to the flow of tears; whilst if the gumma develop in the nasal duct, the small lumen is quickly occluded, and the supervention of mucocele and of abscess is likely to be much more sudden than in the former case.

Polypus of the sac or duct is an occasional cause of obstruction. In April of the present year, a girl presented herself at St. Bartholomew's Hospital, and was admitted as an in-patient with epiphora and a tumour which was diagnosed as a mucocele. No fluid could be expressed either onwards in the normal direction, or backwards in a refluent direction, through the canaliculi. On firm pressure, a rounded body could be felt in the sac, which was supposed might be a polypus. The canaliculus was slit up, and without much difficulty a large probe was passed down the duct. A style was left in for two or three days. Notwithstanding the passage was tolerably clear, epiphora continued. After the lapse of a month, no improvement taking place, it was determined to make a more thorough examination of the parts. An incision was accordingly made through the skin in the direction of the fibres of the orbicularis, the centre of which was opposite the upper orifice of the bony canal of the nasal duct. The sac immediately came into view, and with a little dissection was clearly exposed. The antero-external wall was divided longitudinally, when a little puriform mucus escaped. It then appeared that a mushroom-shaped tumour occupied almost the entire cavity of the sac. It was attached by a narrow pedicle to the inner wall of the sac, and on this being divided came away entire. It was examined by Mr. Linden, who gives the following account:—A few days afterwards the swelling was as large as ever, and on pressure puro-mucus and sanguinolent fluid issued by the side of the style, which was then removed. The swelling gradually subsided, and on May 14th had entirely disappeared. The tears no longer flowed over the cheek, very little scar was left, and the case might be regarded as having been perfectly cured.

In an analogous case recorded by Paul[13] the canaliculus was slit up and the polypus torn out, after which a sound could be introduced into the nose. In the course of a few weeks the polypus reappeared, when it was again torn away, and the whole internal surface of the canaliculus was cauterised by means of a sound dipped in melted nitrate of silver. Severe conjunctivitis followed, and a sound could not be passed. The patient no longer suffered from lacrymation, though the operator thought that this might occur if the superior canaliculus proved ineffective in conducting away the tears, when, as he remarks, a fresh operation would be required. At the time of writing, however, the result was good.

Obstruction of the canaliculi may thus arise from various causes, and the treatment must be intelligently directed to the removal of the special cause acting in each case. Eversion of the lids from age or from paralysis of the orbicularis is difficult to cure; but if accompanied by redness of the inner surface of the lids, the application of sulphate of copper or the mitigated nitrate of silver after instillation of cocaine, will sometimes prove serviceable. Entropion may in slight cases be relieved by the application of collodion or of iodine to the skin of the lid, or in severe cases an oval piece may be removed, or several needles threaded with silk may be passed through the skin at right angles to the lid, the silk being tied over the skin. Obliteration of the puncta may sometimes be overcome by the introduction of a fine probe. Foreign bodies—as cilia, spikes of barley, and dacryoliths—must be removed.

There seems no reason to doubt that epiphora may be relieved by injections into the canaliculi, and sometimes perhaps cured. Pellier de Quengsy[14] gives a case in point. "A rich merchant," he says, "somewhat advanced in years, living in Marseilles, was troubled with so much lacrymation in both eyes that he could neither read nor write. Many internal and external remedies had been applied." M. de Quengsy, after an examination of his eyes, recommended injections, and used first Baréges water and then a solution of sulphate of copper. At the expiration of a month his patient was well. He recommends that the injections should be made for four or five days consecutively every morning and evening, the sac being gently compressed with the finger after it has been filled with the injection, in order that the fluid may be forced into the nose, otherwise by distending the sac they may work more harm than good.

If any circumstances point to the presence of syphilis—as the previous occurrence of chancre, ulcers on the mucous membrane of the throat and fauces, nodes, nocturnal pains in the bones, iritis, or cutaneous affection—it need hardly be said that the local treatment merges into the general, and that the administration of mercury, or (as it is generally in the tertiary period that lacrymal troubles occur) of iodide of potassium would be commenced by every intelligent practitioner. If successful, the disease will soon disappear; if unsuccessful, the antecedent medical treatment will in no way interfere with the adoption of any surgical method that may be thought to be appropriate. More than one instance is on record where perfect recovery took place under alterative treatment without any operative proceeding whatever. M. Larebière gives one case that was communi-

cated to him by M. Galezowski, in which a lady of the mature age of seventy-five—a period of life from which better things might have been expected, and at which heredity could have played only a subordinate and feeble *rôle*—complained to him of lacrymal obstruction; injections, and subsequently catheterism, were practised without benefit, and complete obstruction gradually ensued. Incredulous in regard to her denials, M. Galezowski placed her upon a potassium iodide treatment, and recovery promptly ensued, though not before the daily administration of ninety-three grains had been reached. Many cases are cited by M. Larebière[15] from his own experience and from that of others, in which the iodide of potassium produced rapid amelioration of all the symptoms. In all cases of this nature attention should be paid to the presence of other symptoms of syphilis, and careful examination made of the mucous membrane of the tongue and throat and of the periosteum of the tibia and radius. In cases where a fistula has formed after the bursting of an abscess, the condition of the margin is worthy of particular observation; and cases are on record in which, after ordinary treatment, as the introduction of probes had proved ineffective, though long and systematically employed, relief was immediately obtained and a cure speedily effected by the administration of potassium iodide. In such cases the cutaneous surface of the fistula was more or less ulcerated.

Chronic inflammation of the lacrymal sac, or, as it is sometimes called, chronic catarrh of the sac, is tolerably frequent. By Desmarres, who regarded the symptoms alone, three kinds of tumour were distinguished. In the first, there is only some slight obstruction to the passage of the tears for on pressure, the contents of the sac can be expelled, partly through the duct into the nose, and partly into the conjunctival sac through the canaliculi. This form is of common occurrence. In the second form, the sac is distended, but the contents cannot be expelled from it by pressure, even when made with considerable force. This form occurs less frequently. In the third form, there is a blind internal fistula—that is, the sac is ruptured and the contents have escaped beneath the skin.

The symptoms of chronic catarrh of the lacrymal sac are well known. In the healthy and normal condition the lining membrane of the sac secretes only a little thin mucus, but when irritated the quantity of the fluid secreted becomes increased and its quality changed; the sac becomes distended, and, on pressure, a clear and then a thicker fluid can be made to exude in many instances through the canaliculi. According to some, pus is never seen unless there is some ulceration of the membrane; it may, however, often be seen when there are few or no symptoms of inflammation. Gradually the sac becomes more and more distended till it forms a considerable swelling—in one case as large as a pigeon's egg (Boisson)—at the inner canthus of the eye, often presenting a horizontal depression when the sac is crossed by the tendon of the orbicularis muscle. Several observers have remarked that in the early stages of the affection the swelling is scarcely observable in the morning after sleep, whilst it becomes prominent during the day. The skin over the swelling is not discoloured. The patient complains of no pain, and usually presents himself merely on account of the swelling and the epiphora. Occasionally, though not always, the nostril on the corresponding side is said to be dry.

The causes which lead to chronic dacryocystitis are also those which lead to acute dacryocystitis or lacrymal abscess. Chronic inflammation of the lacrymal sac generally, but not always, precedes acute inflammation of the sac. It is a sort of half-way house, at which the trouble often remains stationary for years or for life, but from which it may easily start forward and march to a disastrous termination. As I shall have to give these causes at some length in my next lecture I shall not dwell upon them here, but rather proceed to consider the more important methods of treatment that have been suggested and practised. It may, however, be remarked that, as a rule, there has been some chronic inflammation of the lower part of the nasal duct in most cases of chronic catarrh of the lacrymal sac. This has led to constriction or absolute closure of the inferior orifice, and this condition it is which the treatment must in general be directed to remove.

How can the removal of such a constriction be best accomplished? At the present moment the method of Arlt, and of many other surgeons, up to Sir William Bowman, is most commonly employed, with the addition lately that the patient is first rendered insensitive to pain by a drop or two of cocaine. One of Sir William Bowman's probes is then introduced into the lower punctum, and made to traverse the canaliculus till it touches the inner wall of the sac. An attempt, generally unsuccessful, is made to pass the probe down the duct. The patient complains of pain, and a little blood appears, because the mucous membrane has been perforated and a false passage made. A week elapses, and either the same performance is repeated, or the inferior canaliculus is slit up, and a Weber's probe is passed down the duct, sometimes with ease, often with great difficulty and the employment of much force. By some practitioners a very large probe is at once passed, and the patient is sent away, it is supposed, cured, though sad experience, I fear, points in too many instances the other way. No doubt in some cases the improvement is immediate and great; but I cannot help regretting that a commission cannot be held, before whom all cases so treated should be cited a year after the operation. In a hundred, would there be fifty, would there be twenty, would there be be even ten, free from trouble?

But there is still another cause, which is worth consideration in regard to the constriction of the nasal duct. May it not sometimes proceed from dental trouble? Careful examination of the superior maxillary bone shows that the alveoli of the canine teeth are in very close relation with the lacrymal passages. Osteitis or periostitis of these alveoli, inducing caries, might easily extend by contiguity to the mucous membrane lining the nasal duct, and the thickening of the membrane might then readily induce first obstruction and then entire occlusion of the lumen. These views, which led me to examine carefully the teeth in all instances that fell under my notice, I find were urged fifteen years ago by M. Abadie.[17]

ON BASIC TUBERCULOUS PHTHISIS.

BY PERCY KIDD, M.D., F.R.C.P.,
ASSISTANT-PHYSICIAN AND PATHOLOGIST AT THE BROMPTON HOSPITAL.

SINCE the time of Louis, the special proclivity of the apex of the lung to become the seat of phthisis has been generally recognised. Various observers have tabulated the results of their experience, and have agreed as to the rarity of this disease commencing at the base of the lung. At the same time, the proportion of cases of basic phthisis to the ordinary apex form has been somewhat differently stated. Louis[1] found a basic origin in 2 cases out of 123, which he carefully investigated. Dr. Walshe gives the proportion as not more than 1 in 60 or 80. Cotton stated it as 2 in 1000. Dr. Pollock[2] says, "I have found 64 cases in a total of 4530 with the physical signs most marked from the commencement of the base." Fagge[3] believes "that it never happens that the tuberculous process spreads upwards from the base of the lung into and through the upper lobe"; and "what has sometimes been called 'basal phthisis' is a distinct affection which has been described above under the name of 'chronic pneumonia.'" This last statement is certainly too absolute as it stands, but from preceding passages it is clear that the distinguished author recognises the existence of true basic phthisis in exceptional cases.

The objects of the present communication are, first, to describe two cases of this rare form of the disease; and, secondly, to examine the statements of authors as to the frequency of basic phthisis and compare them with the results of my own experience. It is important at this point to distinguish clearly between disease of the base and disease affecting the apex of the lower lobe—i.e., that portion of the lung which corresponds to the infraspinous fossa and lower interscapular space. The latter region is very prone to disease, as is well known, and may be occasionally attacked before the apex of the upper lobe. Cases of this sort are not included in the present communi-

cation. I shall now give a brief account of two cases of basic tuberculous phthisis, in which the diagnosis was confirmed by examination after death.

CASE 1. *Symmetrical Basic Phthisis.*—J. W——, aged fifty, a carpenter, was admitted on March 7th, 1884. No family history of phthisis; previous health good. Five months previously the patient caught cold, had shivers, and was confined to bed for thirteen weeks with pains in the back and side, cough, expectoration, and loss of flesh. On admission the patient was emaciated, his respiration was very rapid, and his temperature was 103°. The chest was hyperresonant. At both posterior bases slight dulness and subcrepitant râles existed. At the right base the breath sounds were weak, the expiration was prolonged, and vocal fremitus diminished. At the left base there were tubular breathing and increased vocal resonance. The sputum was examined, and found to contain tubercle bacilli in fair numbers. On March 22nd, at both apices, slight dulness with weak breath sounds and scanty subcrepitant râles were present. At the right posterior base, tubular breathing and bronchophony. At the left base, breath sounds weak. Abundant subcrepitant râles were heard on both sides, and dry rub in both axillæ. From this time the patient began to fail, physical signs appeared in the upper parts, cavities developed at both bases, and the patient sank on July 8th.

Necropsy.—Firm general pleuritic adhesions on both sides. Right lung: Middle and lower lobes completely riddled with thick-walled trabeculated cavities; at the base the cavities were bounded by a rim of extremely dense fibroid tissue. The upper lobe contained a small cavity at the apex, but was elsewhere spongy, though studded with a few tuberculous nodules. The left lung at its upper lobe was spongy throughout, and only contained a few small nodules. The posterior part of the lower lobe was occupied by a large trabeculated cavity, with dense fibroid walls at the base; anterior parts spongy. Spleen amyloid. Tubercular ulceration of the intestine. Mesenteric glands caseous.

This was an extremely interesting and uncommon example of tuberculosis attacking both bases simultaneously and spreading into the upper lobes subsequently.

CASE 2. *Phthisis: physical signs most marked at the left base.*—G. P——, aged twenty-one, a clerk, was admitted in July, 1885, and was spitting blood at the time. The hæmoptysis persisted for two or three days. Three months previously he caught cold, and since then had had cough; six weeks before admission he had an attack of "pleurisy and inflammation of the lung. On examination, there was diffused crepitation over the whole left lung in front. Posteriorly, there was dulness from the apex to the base, more marked below, with loose crepitation throughout. There were marked cavernous signs in the lower interscapular space extending down to the base close to the spine. On the right side there were scattered subcrepitant râles over the front and at the posterior base. Tubercle bacilli were present in the sputum in abundance. The patient spat up a small quantity of blood on two occasions in September. After that time there was no return of hæmorrhage until the end of November, when he had a fatal attack of hæmoptysis.

Necropsy.—Firm pleuritic adhesions throughout over the left lung; loose adhesions over the right lung. The left lung at its lower lobe contained numerous large cavities, surrounded by extensive caseous tracts and nodules. Two of the cavities at the base contained a small aneurysm of the pulmonary artery, one of which had ruptured and caused the fatal hæmorrhage. At the base, close to the vertebral border, there was a group of cavities of sinuous outline, with tough fibroid walls. The upper lobe showed similar but less extensive disease; the caseous masses were less abundant, and the cavities smaller and fewer in number. None of the cavities in this lobe had such an old appearance as the group of cavities at the base before alluded to. The right lung was spongy, and studded with some tuberculous nodules. The intestine showed tubercular ulceration. The oldest disease seemed to be situated at the base of the left lung.

Dr. Pollock believes that basic cases, as a rule, are of a chronic type. The duration of those just described was approximately nine months and seven months respectively. These are the only cases of true basic tuberculous phthisis that I have met with in 412 cases of phthisis in which I made the post-mortem examination myself. The first case was an undoubted instance of primary basic tuberculosis. In the second there was more disease of the upper part of the lung than in the first, but the disease was more extensive and of older date at the left base than elsewhere, and therefore I think we may fairly consider that here also the phthisis was primarily basic. The proportion of basic cases, therefore, among those that I have examined after death would be 1 in 206. I think it very likely, however, that a larger number of post-mortem examinations would still further reduce this proportion, and probably 1 in 500 would not be far wide of the mark. If so, then the proportions given by Louis, Walshe, and Pollock are too high, although, no great value is to be attached to attempts to state the proportion in exact figures. I believe that Cotton and Fagge are nearer the truth than those who give it as 1 in 60 or 80, and I think it is worth while to endeavour to account for the comparatively high proportion just quoted. The fact that Louis found 2 cases of basic origin in a total of 123 is not sufficient to warrant any generalisation. His numbers are far too small for this purpose. Dr. Pollock's statement cited above shows that he rests his conclusions on the preponderance of the physical signs at the base of the lung. I think, however, it can be shown that reliance on the clinical method in attempting to settle this point is liable to certain fallacies which may be considered under two heads: (1) the difficulty in certain cases of diagnosing the nature of disease of the base of the lung; (2) the latency, as far as physical signs are concerned, of comparatively old apex disease in some instances where there are marked signs at the base. In other words, cases of non-tuberculous basic disease may occasionally be included in the list owing to the difficulties of diagnosis, and, as I believe more often happens, physical signs may be at first confined to the base, or be most marked there, although all the time there is older disease of the apex which gives little or no evidence of its presence.

I shall now give abstracts of cases that illustrate these points:—

Cases of Uncomplicated Non-tuberculous Basic Disease.

1. J. W——, aged thirty-two, a plasterer, seen as an out-patient. His history was that seven years ago he had an acute chest attack, beginning with rigors, vomiting, headache, and cough, which laid him up for nine weeks. He attended subsequently as an out-patient under Dr. F. T. Roberts, and made a good recovery. The cough and expectoration, which had quite disappeared, returned again two years ago, and during the last nine months he had wasted enormously. He had "pleurisy" four months ago, and since that time the expectoration has been very offensive. The patient was anæmic and cachectic-looking; breath and expectoration extremely fetid; fingers clubbed; chest well formed. On the left side, posteriorly, there was marked dulness over the lower half, with weak tubular breathing, bronchophony, and increased vocal fremitus, most marked just below the angle of the scapula. Very scanty moist râles on coughing were heard over the same area. There were no other abnormal signs on either side. Diagnosis: cirrhosis and bronchiectasis of left base. The patient did not improve under antiseptic and tonic treatment. Marked cavernous signs, with gurgling râles, appeared at the left base behind, and the patient was admitted into the hospital three months later. The sputum was then examined, and no tubercle bacilli could be found. Shortly after admission he became much worse; the temperature rose and assumed a hectic type, signs of pleurisy on the right (i.e., the sound) side developed, and he sank in a few days with septic symptoms.

Necropsy.—General pleuritic adhesions on the left side, very dense over the lower lobe. Lungs: The left lower lobe was converted into a system of trabeculated cavities of bronchiectatic appearance, surrounded by indurated fibroid tissue. In the upper lobe there was slight but uniform cylindrical bronchiectasis; on the right side fibrino-purulent pleurisy. There was slight thickening of the interlobular septa of the upper lobe, which microscopically proved to be of a fibrinous character (? lymphangitis), and was associated with commencing dilatation of the smaller bronchi. The contents of the cavities were examined for tubercle bacilli, with a negative result. No tuberculosis in any part of the body.

The following is another case in some respects resembling the last:—

2. D. S.——, aged thirty-seven, a stout young woman, came as an out-patient in March 1884, with the following history. Had coughed off and on for ten years which was

Digitized by Google

worse during the last two winters. For the last twelve months she had been getting very stout, although she had not taken cod-liver oil for five or six years. The cough had been more severe the last six months, and the expectoration had been profuse and yellow, but not fetid. Over the left apex there was slight dulness and weak breath sounds, with prolonged expiratory murmur and scanty bubbling râles. At the base, posteriorly, there was marked dulness from the midscapular region downwards, with intense cavernous breathing, pectoriloquy, increased vocal fremitus, and gurgling râles. These signs were most marked just below the angle of the scapula. At times a few subcrepitant râles were heard in the right interscapular space, but otherwise the physical signs hardly varied at all. The patient gradually improved under tonic treatment with antiseptic remedies (namely, tar and creasote). The sputum was examined several times, but no tubercle bacilli were ever found. The patient has continued to attend off and on from the first, and when last seen, in March, 1886, her general condition had decidedly improved, and the expectoration was less profuse, but the physical signs showed little or no change. She had one or two slight attacks of hæmoptysis from time to time, but had not lost flesh. The diagnosis was—cirrhosis of the left base, with small cavities, probably bronchiectatic in origin, and an early stage of the same disease in the upper lobe.

The absence of wasting from the first might be thought almost to exclude phthisis, but I have seen at least one case in which the patient, also a young woman, remained for some months extremely stout, although suffering from true tuberculous phthisis. The course of the present case has so far justified the view that was taken of it. But when I first saw D. S—— it was important for diagnostic and prognostic purposes to convince oneself of the absence of tuberculosis. Repeated examination of the sputum seemed to warrant this conclusion, and enabled me to give a comparatively favourable prognosis. I do not venture to assert that the foregoing two cases would be generally included under the head of "tuberculous," and I only give them as good illustrations of non-tuberculous basic disease, and as bearing on the next group.

Cases of Non-tuberculous Basic Disease complicated by subsequent Tuberculosis.

1. R. O——, aged forty-nine, a labourer, came as an out-patient in 1882. He stated that for the last two years he had suffered from cough, especially in winter, and from profuse expectoration. Eighteen months ago he had congestion of the lungs, and was laid up for five weeks. Six months later he had profuse hæmoptysis, lasting for seven or eight days. The expectoration had been offensive for the last four months only. The patient was a muscular man, but very anæmic, and his breath and expectoration were intolerably offensive. At the right posterior base there was dulness with marked cavernous breathing, pectoriloquy, and moist râles, more especially at the angle of the scapula. There was slight dulness in the left interscapular region, with scanty subcrepitant râles, slightly increased vocal resonance, and prolonged expiration. The patient gradually got worse. The râles at the right base became more gurgling and the breathing more intensely cavernous. He was admitted into the hospital shortly afterwards. The sputum was examined, but no tubercle bacilli were found. The diagnosis was uncertain, and seemed to lie between a small empyema freely communicating with the lung and fibroid lung with bronchiectasis. An abscess developed in the abdominal walls, phlegmonous erysipelas followed, and he sank a month after admission.

Necropsy.—Marked cirrhosis of the right lower lobe, with small irregular cavities around the entrance of the main bronchus. There were also a few pigmented nodules, like miliary tubercles, in the upper lobe. The left lung contained one small cavity at its apex, with some few tuberculous nodules immediately around it, but elsewhere was healthy. There was also commencing tubercular ulceration of the intestine.

The disease here was evidently a chronic pneumonia with subsequent tuberculosis. The sputum was examined only once, I believe, and just after admission. Possibly more frequent examinations would have revealed the existence of tubercle bacilli, which would have still further added to the difficulties of diagnosis.

2. J. S——, a labourer, was admitted in a moribund condition in March, 1886. The patient was too ill to examine carefully or question much, and died a day or two after admission.

Necropsy.—The left lung was firmly adherent to the chest walls throughout, and extensively excavated in its upper portions, the lower parts being studded with tuberculous nodules. The right lung was adherent throughout, but less firmly. The upper and middle lobes were enormously distended and spongy, containing a few nodules only. The lower lobe was extremely contracted, and hardly as big as one's fist. This lobe had a bright scarlet colour, like the lung of an infant, contrasting strangely with the pigmented condition of the rest of the lung. The lower lobe was riddled with cylindrical bronchiectases, which were filled with muco-purulent secretion. The intervening tissue was imperfectly spongy, but contained no tuberculous lesions.

From the atrophied state of the lobe and its bright-red colour it is probable that there had been more or less collapse in early childhood, with secondary bronchiectasis. This disease was evidently antecedent to the tuberculosis. If this patient had been seen before tuberculosis developed, the right base would certainly have given some abnormal physical signs which might have suggested the diagnosis of basic phthisis. Still more, if the patient had been under observation when the phthisis was actually developing, the idea of a basic origin would have been strongly supported.

3. J. H——, aged forty-two, a steward, admitted in March, 1884, with this history:—Six months ago he caught cold and had pleurisy at Naples. Since that time he had had a cough, and six weeks ago his expectoration became blood-stained. Physical examination of the chest disclosed dulness on the right side behind over the lower half, with weak bronchial breathing and subcrepitant râles. At the left apex behind there were a few similar râles. The liver could just be felt below the ribs' margin, and was tender. The liver dulness reached the fifth rib in front. The patient suffered much from diarrhœa off and on, and the sputum was usually blood-stained, and of a brick-dust colour. The diagnosis was very uncertain, and lay between malignant disease and phthisis. There is no statement in the notes as to examination of the sputum, but my impression is that tubercle bacilli were found on one occasion. The patient died a month after admission.

Necropsy.—There was a large abscess of the right lobe of the liver, which had perforated the diaphragm and communicated with a large abscess cavity in the lower lobe of the right lung. There was some scattered miliary tubercle in the upper parts of this lung, and the left lung at its apex contained a small cavity, and miliary tubercle was scattered through its substance. No caseous masses. The colon showed old ulceration, with great thickening, probably of dysenteric origin. Microscopical examination revealed extreme fibroid thickening of the walls of the colon, and there was no trace of tuberculosis.

4. E. J. W——, aged thirty-three, a nursery governess, admitted in November, 1882, with a very marked family history of phthisis. She had suffered from congestion of the lungs in 1877, 1881, and in May, 1882. Since the last attack she had been troubled with cough, expectoration, and shortness of breath. At the left posterior base, there was dulness, deficient breath sounds, and spongy friction. Physical signs of disease gradually spread to the other parts of the lung, and she sank in April, 1883.

Necropsy.—The left lung contained numerous large cavities in its upper lobe, with marked nodular caseous consolidation. The lower lobe contained radiating fibroid bands, and the bronchi were dilated. In several places towards the base the bronchi presented saccular expansions. There were some scattered miliary tubercles and caseous nodules. The right apex contained a large cavity, and the lower parts showed nodular lesions. The basic disease here was a cirrhotic non-tuberculous one in the first instance, and clinically gave the signs of pleurisy. Tuberculosis developed subsequently.

(To be concluded.)

MR. GEORGE BARRY, a trustee of the joint parishes of St. Luke, St. Giles, Cripplegate, and St. Botolph, has, in a report of a recent visit to parish properties, called attention to an insanitary spot in the neighbourhood of Piccadilly, where kitchens with only pavement gratings to admit light and ventilation are let out to families at 1*s.* 6*d.* per week. And this within sight of the windows of noblemen's mansions!

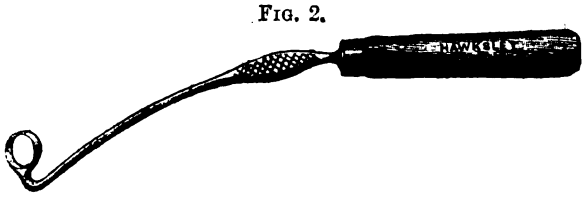
ADENOID GROWTHS IN THE PHARYNX.

BY SIR WM. B. DALBY, F.R.C.S., M.B. CANTAB.,
AURAL SURGEON TO ST. GEORGE'S HOSPITAL.

IN order to estimate the position which adenoid vegetations in the vault of the pharynx, in regard both to their diagnosis and removal, occupies in the domain of surgery at the present time, it must be borne in mind that, with the exception of two or three solitary observations, up to the year 1868 the existence and gravity of the disorder were not recognised It was in this year that Dr. Meyer of Copenhagen published his first account of the subject, and in the following year brought the matter before the Royal Medical and Chirurgical Society. At the International Medical Congress of 1881 several papers on adenoid vegetations were read, and the various methods in use for their removal were most fully discussed. Thus it will be seen that the intermediate twelve years had served to render familiar in 1881 what was practically unknown in 1868. Taking into consideration these papers and their discussion, as well as the number of surgeons who now habitually treat this affection, the extreme facility with which the growths can be recognised by an examination with the forefinger gently introduced behind the soft palate may be said to be acknowledged; and should anyone question this proposition, it is open to him to verify it in any case which presents the usual characteristics of the affection by first examining a patient in whom the vault of the pharynx is healthy, and immediately afterwards the adenoid case. The difference of the two is too striking to escape even the observation of one who does this for the first time. Indeed, it was by an examination of this sort that Dr. Meyer discovered the growths in his first case. A rhinoscopic examination may be regarded therefore as supplementary to this, and in many cases, even in the most skilful hands, as impracticable—as, for example, in the case of young children. As a complete account of the methods adopted by various surgeons to effect the removal of adenoid growths between the two periods which I have named—viz., 1868 and 1881—may be found in Mackenzie's Manual, in the following brief remarks the history of the subject and the practice of others may be taken as read.

If one thing more than another stands out in relation to what is written, said, and done in connexion with this matter, it is the necessity of tolerance for other methods whilst advocating our own, and for the following reason: that it is characteristic of the complaint that if the growths are removed in any way, so long as they are completely removed, the patients get well both as to nasal breathing and hearing. To illustrate what I mean, I may be permitted to refer to a point which interested me very much in 1883. At the Congress, Dr. Guye of Amsterdam had strongly recommended a plan of scraping away adenoid vegetations from the pharynx by the nail of the right forefinger, and he had not limited himself in this to any class of cases. I knew also that my friend Mr. Cresswell Baber of Brighton habitually practised this plan without any selection of cases. It had appeared to me that if this were possible, nothing could be more satisfactory than to have in their removal the guidance of the sensitive finger which had detected the presence and the position of the growths; and I could readily understand how in the case of young children, when the growths were soft and friable and not in very large quantities, this could be done. When, however, as often happens, these growths are very numerous, of great size, and extreme toughness, I could not understand how the finger-nail of anyone could so embed itself in the tissue as to cut it clean away. I therefore had made for me a species of mechanical finger-nail constructed of steel, on a principle similar to Capart's spoon, but unlike it in action and construction (to which I shall refer presently), and with the help of this I could remove these growths with great completeness and with the most happy results. (See Fig 1.) On the date mentioned—viz., Oct. 1st, 1883—I met Mr. Baber, and in discussing this question of common interest no doubt was left in my mind as to the fact that some finger-nails (notably Mr. Baber's) can be found sufficiently strong, and of such formation, to effect in the matter of operation all that is required without having resort to any other method. What, however, can be done with the finger-nail only in individual instances ("individual" as applied to the operator) may be done by anyone if the steel nail is employed.



There are several considerations which have commended themselves to me in this method of removing adenoid vegetations from the pharynx. In the first place, when the mouth is held open with a Mason's gag, the pharynx can be most completely explored with the forefinger, and the amount of vegetations, their size and position, can be most satisfactorily estimated. The instant after this is done the steel nail can be fixed to the finger, and they can be scraped away at leisure. When I say "scraped away," I mean that the steel nail can be embedded in them and made to cut them away. The head being bent forward at the time by the left hand placed on the vertex, the blood, which flows very freely, escapes by the nostrils. It will be observed that the instrument is so made that the tip of the finger is exposed, and this is most useful in estimating by touch what is being done. Although the whole proceeding does not occupy long, inasmuch as it is most unpleasant and in some degree painful, it is convenient and desirable in many cases, especially

FIG. 1.

in young and timid children, that ether should be given. The position in which the head is held prevents the possibility of blood passing into the larynx during an inspiration. Although at one time I was inclined to repeated rather than to immediate operation, I am bound to say that latterly I have found not one of the least of the advantages of the steel nails is that the pharynx is frequently cleared at one sitting—in the case of young children, cleared so completely that a fortnight after the operation, when the swelling which follows it has subsided, the mouth can be kept closed both waking and sleeping; the "deadness" of speech, so indicative of the affection, disappears; the passage through the posterior nares is restored; the Eustachian obstruction, with its accompanying deafness and the liability to it, is gone. In short, the results of this method have recently proved so satisfactory that in five cases of children in which I employed it (Mr. Braine giving ether in each) during one week no further removal is now necessary. In older patients, where the growths are tougher and very abundant, more than one sitting is generally required. The plucking away in pieces by Löwenberg's forceps will no

FIG. 2.

doubt succeed in getting rid of the vegetations, but this entails several sittings, and some patients and their friends are apt to shirk what is very disagreeable before the completion of the treatment. It is therefore better to avoid this when possible. Moreover, it is undoubtedly a great advantage to be able to feel with the finger the vegetations as they are being scraped off. This cannot be done with Löwenberg's forceps (or with Woakes' modification, which has the advantage of increasing the cutting surface), or with what is otherwise a most useful instrument—viz., a curved ring knife, which Mr. Hawksley constructed for me before the steel nail. (See Fig. 2.) With this knife, the ring being passed up into the pharynx behind the soft palate, the growths can be by a sweeping movement cut away. This knife is made on the same principle as Gottstein's, and although I have found it more easily moved about in the pharynx, I have seen cases where, in other hands than mine, the whole pharynx has been cleared at one sitting of abundant tough adenoid growths by Gottstein's knife. Notwithstanding the varieties in methods that are now in use, Dr. Meyer still, I believe, adheres (and with excellent

Digitized by Google

results) to the plan which he described in what may be most truthfully said to be his classical paper on this affection in the Medical and Chirurgical Transactions—viz., his flexible ring knife passed through the nares into the pharynx, guided throughout its movements by the forefinger of the left hand; but as the unpleasantness of having the ring knife passed through the nares can be avoided by operating through the mouth in one of the many methods now adopted, his mode of attack, so to speak, is, from what I can learn, not followed out by others.

Looking back to a period when this affection was unknown, and the precise cause of the characteristic intonation in these patients was unsuspected, it is curious to notice how absolutely familiar Dickens was with the peculiarities of voice which marks the subjects of adenoid vegetations. He must have come in contact with some of them when he so accurately reproduces the voice in one of the characters in "Oliver Twist." There he makes the boy Barney (one of Fagin's gang) say "stradegers id the next roob," and "ah! ad rub 'uds too, from the cuttry, but subthig in your way, or I'b bistaked." From the context we may fairly suppose he believed this intonation was indicative of race, and he introduces it by way of emphasising the generally disagreeable peculiarities of the characters he so graphically depicts; but in this particular he certainly does Barney an injustice, for adenoid vegetations are to be met with in "all sorts and conditions of men," living under the most favourable or unfavourable circumstances, and in many latitudes. That they are frequently present in several of the same family cannot fail to be noticed (I have seen four in one family), and from the recollection of parents as to their own breathing and hearing in childhood, the tendency to abnormal adenoid development would seem to be inherited; but as the parents have arrived at the time of life when this enlargement has disappeared, it is not easy to establish this point. Besides the departure of three symptoms—viz., the tendency to Eustachian obstruction, the consequent deafness (which generally directs attention to the trouble), and the nasal obstruction—which follows the removal of adenoid vegetations, there are other advantages to be reckoned, such as the better prospects of recovery in case of diphtheria or scarlet fever occurring, with an empty rather than a blocked pharynx, as well as the better chances of the middle ear escaping destruction during these diseases. The improvements also of the general health, with free nasal breathing, as well as the diminished tendency to bronchial affections, require only mention to be appreciated.

Savile-row, W.

THE ETIOLOGY OF TYPHUS FEVER,

ILLUSTRATED BY A SERIES OF RECENT OUTBREAKS IN DUNDEE AND NEIGHBOURHOOD.

BY ROBERT SINCLAIR, M.D.,
PHYSICIAN TO THE DUNDEE ROYAL INFIRMARY.

(*Concluded from p. 574.*)

Outbreak No. 10.—Mrs. M——, aged fifty-three, resided at 2, John-street (Central). She and her son occupied two small attic rooms, which, according to Dr. Stalker, were very close and ill-ventilated, owing to the windows not opening, and the only air that could reach them entering by the door after doing duty in the stairs and flats below. She had not been near any house in which there was illness for months, but she confessed to insufficient feeding. She sickened of typhus on July 3rd, was admitted on the 13th, and recovered. Dismissed Aug. 25th. Her son was admitted on Aug. 18th, the sixth day of the fever. Was the son infected directly from the mother? I think not. To accept this explanation would necessitate belief in a thirty days' incubation-period, of which we have no collateral evidence. Was he infected by her indirectly through fomites? Or was his a case of generation of the poison *de novo?* After the mother's removal, the house, bed, personal clothing, and furniture were subjected to the usual cleansing and germicidal measures by the sanitary department. If my friend, Dr. Anderson, is prepared to certify that no infective material remained in the house after these measures, we shall be free to accept the theory which, in my opinion, is the only tenable one for the origin of the mother's attack—namely, a new development of the poison; and there is this to be said for the latter view, that although the house was cleaned the son continued to live in precisely the same insanitary conditions which preceded his mother's illness.

Outbreak No. 11.—Mrs. S——, aged fifty, 23, Edward-street (West Central), half a mile from the last outbreak, was admitted on July 11th, the fifth day of her illness, as a medical case. On the day after her admission she had a well-marked typhus rash. The attack was sharp and left patient very weak, although it terminated on the ninth day. The only illness for a long time in the acquaintance or neighbourhood of this patient happened to be in the next house, where she frequently visited. In it there were two rooms occupied by seven inmates. The head of this house had been out of work for some time, and the family had therefore been rather poorly fed, and two of his children had had febrile illnesses, which lasted respectively (including convalescence) four and seven weeks. These cases were not recognised as typhus, but there can be little doubt that they were so. While the children were ill Mrs. S—— visited them very frequently, and helped their mother to nurse them. But a full and exhaustive investigation failed to connect this outbreak with any preceding case.

Outbreak No. 12.—A. T——, aged thirty-three, a Swedish sailor, arrived in Dundee on August 27th, having left Quebec in a sailing vessel forty-eight days previously. He sickened on August 19th, and was seen by Dr. Gibb on the 27th in the dark forecastle occupied by himself and four others. This place was very dark, had no portholes or windows, and emitted a stench so powerful as to render breathing in it very unpleasant. No other case of illness had occurred on the voyage. He was immediately removed to the infirmary. I saw him on the day after admission, and noted a dusky aspect, a typhus odour from the breath and body, an enlarged spleen, and a typhus rash over the abdomen and back. The morning remissions of temperature in this case in the second week were much more pronounced than we usually find them in typhus. On the eleventh day the morning temperature was 101°, the evening 104·4°; twelfth day, morning 100°, evening 101·2°; thirteenth day, morning 99°, evening 102·6°; fourteenth day, morning 100·4°, evening 102·8°; fifteenth day, morning 99·8°, evening 103·8°; sixteenth day, morning 98·6°, evening 102·4°; seventeenth day, morning 98·4°, evening 101·4; eighteenth day, morning 98·4°, evening 100°. On the twenty-first day the temperature both morning and evening was normal. On the fifteenth day of the fever I dictated the following note which will sufficiently show the doubts which then existed in my mind:—"Skin perspiring; copious eruption of sudamina on abdomen. Rash still obvious on back, but nowhere petechial. A few spots still somewhat papular, but rather less so than when first observed. No mottling from the first. Tongue coated with a dirty yellow fur, and inclined to dry in centre. Aspect still rather dusky. Has taken milk better for the last twenty-four hours. Bowels not moved since three days ago, when he had one rather loose stool, green in colour, certainly not pea-soupy, and without medicine. One small-formed stool, pale yellow, two days ago." Now sudamina are well known to be much rarer in typhus than in enteric fever, although less rare under than over forty years of age. The temperature remained above the normal standard until the evening of the twenty-first day; it was not only more decidedly remittent than we are accustomed to in typhus, but on the last five days it was truly intermittent; in all these three respects resembling enteric fever in its later stages rather than typhus. I do not raise the question whether there may have been in this case and in the case of S—— a double infection of typhus and enteric. Where did this man get his typhus? The time that elapsed between the departure of his ship from Quebec and the onset of his illness—forty days—puts infection from Canada out of the question. Was it due to fomites? It may have been; but if so, why did the poison lie dormant so long in this pestilential hole? Was it not more likely to have been generated in those conditions which Dr. Gibb describes, and which remind one of Howard's description of our prisons a century ago? Several months since, I asked the medical officer of health for Quebec if any typhus existed in that port during the sojourn of the ship there, but I have received no reply. I traced the ship for three weeks after she left Dundee, and no fresh cases had occurred on board during that time.

Outbreak No. 13.—J. A——, aged forty, an umbrella-mender, who resided with his wife and six children in two small ill-ventilated rooms, at 3, Castle-court (Central). He rarely left his house (sometimes not for a week), in which he did all his work; he had not been in any house but his own for months, and there was no fever in the neighbourhood. He was sent in by Dr. Stalker on Oct. 13th, the eighth day of the fever, with a typhus aspect and rash, which had been preceded by rigors and headache. Here, I think, we are shut up to one of two explanations—either that the poison was manufactured in his overcrowded dwelling, or that it was introduced by one of the numerous umbrellas brought to him for repair. But typhus centres are not places where such avoidable luxuries are in much demand; and the man assured me that his customers belong chiefly to the well-to-do classes.

Conclusion.—My narrative is ended. It affords ample evidence of the contagiousness of typhus, of its intimate association with human misery, and its amenability to prompt sanitary action. These are the truisms of its natural history. The question that will be asked, and that ought to be asked, is—Does all this dry detail, this tracking of cases, this inspection of houses, bring us one whit nearer a solution of the problem of the origin of the disease? Which of the two conflicting doctrines are we to accept? Is typhus always the result of specific infection from an antecedent case? Or can it be generated *de novo* from the concentrated and putrid exhalations of human beings? No one, I presume, will deny that the clinical history of the disease warrants us in concluding that there is a specific typhus poison. But some of us may be disposed to hesitate before assenting to the creed of Dr. Davies, who "would as soon believe in the spontaneous generation of human beings as in the spontaneous generation of typhus."[1] At the same time I freely allow the difficulties of the doctrine which is associated with the great name of Murchison, that the poison can be developed by these squalid conditions, in which typhus is most commonly seen. The difficulty of proving a negative we all know; and it would be idle to deny the strength of the position of those who hold that we are not hastily to assume an independent origin of typhus simply because it has not been possible to trace a connexion between every new case and an antecedent one. I set to work to seek out the story of these outbreaks simply in a spirit of inquiry, and with a determination to probe every detail to the bottom. I confess to having long inclined to the new generation side of the controversy. A man who has been seeing typhus pretty steadily for fourteen years could hardly avoid having an opinion on the subject. But I have not allowed personal bias to suppress or gloss over a single fact which has come under my notice. So far from this, follower of Murchison as I am, patient inquiry has in many cases established a contagious origin where at first a new generation of the poison seemed the only possible explanation. Not till long after I had begun my investigation did I hear from Dr. Watt his interesting account of the importation of typhus by the Glasgow tramp. It tells I confess, very strongly, against me. But we have no evidence of its spread to more than two persons in the dense and dirty population of the Bog.

What are the broad facts of these outbreaks? From Feb. 20th, 1884, when the last cases of the previous epidemic were safely lodged in the infirmary, Dundee was free from typhus till the end of September of the same year, when Dr. Watt tells us the disease was introduced by a Glasgow tramp. That a tramp from Glasgow might easily have typhus is undeniable; because Dr. Russell, the medical officer of health for that city, wrote some months ago—"You may take it that typhus never is extinct in Glasgow. There has not been a day during my official connexion with Glasgow (twenty years now) when we had not cases in our wards." Only two undoubted cases can be traced to the tramp. Two months after the Lochee boy's death typhus appeared in Miller's Pend, fully a mile and a half distant from Lochee. The removal of an infected family speedily transferred it to Milne's East Wynd close by. In January we had outbreaks in Lochee, Butterburn, and Lilybank-road—the extreme north-west, northern, and eastern districts of Dundee. It appeared in the centre of the town (Ramsay's Pend) and in the north-west (Mitchell-street) in March; in Dudhope-crescent (the centre again) in April. Then we had the Invergowrie case in June. In July we had two cases from Dudhope-crescent after it had been absent from there for two months and a half. In the same month it cropped up in Edward-street. Then we had the Swedish sailor—clearly an imported case—in August; and, finally, the umbrella-mender, who rarely left his house, sickened on Oct. 5th, at a time when, with the exception of the sailor, who was conveyed straight from his ship to the infirmary, typhus had been absent from Dundee for three months.

The nomadic habits of some of those who suffer from typhus must not be forgotten, and due weight must be allowed for the action of fomites; but if this unfortunate tramp was the cause of all the typhus we have had for fully twelve months in Dundee, why, let me ask, did the outbreaks not show some reasonable relation in time to his attack, and why did they not follow the ordinary streams of human intercourse, instead of cropping up at intervals of time and space which seem to preclude any possibility of connexion with him and with one another—a connexion which a very exhaustive inquiry utterly failed to establish? The case of the boy from New Mill of Gray seems to me to be one of the most striking instances possible of a fresh and unusual generation of the poison. His surroundings were most comfortable. The only case of typhus in Dundee of which we have any knowledge when he sickened, and for twenty-two days before, was at 11, Milne's East Wynd, and he was never within 570 yards of it. Now, there is no case on record of the disease spreading through the open air. "It never spread from the London Fever Hospital," says Murchison, "to neighbouring houses, even when the hospital was one of a row of houses in Gray's-inn-lane." And when the hospital occupied its second site at King's-cross, on the same plot of ground as the Small-pox Hospital and within a few yards of it, Dr. Tweedie states that, notwithstanding the certainty with which its own officials contracted typhus, there had been no instance of this fever among the officials of the Small-pox Hospital during eight years."[2] If overcrowding, defective ventilation, and filth are only predisposing causes, we must assume the omnipresence of the specific virus, ready to swoop down at any moment and take root in favourable soil. But the facts point quite the other way. We know that the poison is very easily weakened and destroyed by fresh air and a sanitary environment. The disease never shows itself first except in the midst of insanitary conditions, and if it only appears in such conditions "it seems fair," as Murchison says, "to assume that the appreciable conditions, and not an omnipresent and indestructible poison, constitute the primary cause of typhus."[3] But, even granting that analogy warrants the conclusion that the virus of typhus contains a specific micro-organism, the doctrine of generation of the disease *de novo* is by no means overthrown, because the microbe may only be capable of activity under those insanitary conditions in which the disease always first manifests itself, and in the midst of which it unquestionably shows its greatest virulence. I am not aware if this observation has been made before; if so, I have never heard of it. But during this inquiry I was positively struck with the frequency with which the first cases of outbreaks that the utmost care failed to connect with previous cases occurred in attic rooms. These rooms, being the coldest in the house, are not likely to have their windows opened too often; and being at the summit of the building, and often at the summit of very badly ventilated staircases, are obviously exposed to greater risk of being filled with vitiated air than the apartments lower down. The bearing of this observation on the causation of typhus is perfectly obvious if we allow the possibility of generating the poison. But having said all this in favour of the doctrine to which I give my own adherence, I am bound in all fairness to acknowledge a remark that was constantly on my lips while conducting this investigation—that the marvel to me was, not that typhus sometimes originates in the fever dens of Dundee, but that it is ever absent. On the other hand, it must be said that the precise amount of overcrowding, defective ventilation, and filth, and the state of the atmosphere and temperature, which presumably are necessary for the generation of the poison, are yet known to us, and are probably not always present. And if anyone asks, Why do these same or similar conditions not develop the virus of typhus everywhere; why, for example, should typhus bear the character of an endemic malady in Ireland and Russia, when it has found difficulty in gaining a footing in Asia, and has not occurred

in the greater part of the African continent; why did typhus not appear in the United States and Canada till its introduction by the Irish immigrants? why in America does it chiefly affect the eastern seaboard and spread mainly among the Irish who have landed there?—my answer is that each family of the human race and each climate has its own proper specific diseases. And if I am further asked, Why has typhus never gained a footing in Australia, Polynesia, and New Zealand?—I cannot refrain from replying that the lands whose indigenous quadrupeds are stunted, and whose evergreen forests are the marvel of the traveller, may, for aught we know, be inimical to the generation and spread of the poison; moreover, these countries are in the European sense new countries, and, if we only give them time, the habits of the Celtic Irish may yet succeed in developing typhus there as they have developed it at home.

Whatever may be thought of the views I have ventured to submit, I believe that there will be agreement on two points: first, that the doctrine of the independent origin of typhus will, wherever accepted, exert a more quickening effect on local authorities than its opponent; and secondly, that the history of these thirteen outbreaks, occurring for the chief part in the most densely populated districts of Dundee, and affecting only fifty-four persons in all, demonstrates, beyond the shadow of a doubt, the ability and success with which our public health work is conducted by Dr. Anderson, Mr. Kinnear, and the other officials of the sanitary department. But for their efforts, the labouring classes of Dundee might now be suffering from a typhus epidemic of overwhelming magnitude and mortality.

ON A CASE OF ACUTE TONSILLITIS IN A SUBJECT OF TERTIARY SYPHILIS OF THE PHARYNX.

BY H. W. G. MACKENZIE, M.A., M.B., M.R.C.S.,
RESIDENT ASSISTANT-PHYSICIAN TO ST. THOMAS'S HOSPITAL, FORMERLY CLINICAL ASSISTANT IN THE THROAT DEPARTMENT.

CASES in which the soft palate forms adhesions to the posterior wall of the pharynx are not very rarely seen among patients who have been the subjects of syphilitic ulceration in these parts. The appearance which such a case presents on examination of the fauces is not a little bewildering to the uninitiated. Once seen and understood, however, it will afterwards be easily recognised. There is no palatine arch, and probably no uvula. The roof of the mouth and pillars of the fauces, hardly to be recognised as such, are quite continuous with the posterior wall of the pharynx. The naso-pharynx is seldom quite shut off from the rest of the pharyngeal cavity. Behind the edge of the hard palate there may be a perforation of the soft palate, or it may be that one of the posterior pillars has not become completely adherent, thus leaving in either case a small round opening sufficient for the passage of air. The adhesion probably begins from below. If there is a perforation already formed in the soft palate, then, as Schech has pointed out, the adhesion will in all probability become complete. In this case the movements of the soft palate are much impaired, and to a certain extent unnecessary, on account of the permanent communication between the two cavities. Thus the soft palate is allowed to remain in contact with the pharyngeal wall. In the absence of perforation the continued passage of air will probably prevent complete adhesion taking place. The process must be a very gradual and nearly a painless one, otherwise it is difficult to explain why such patients have allowed it to go on without applying for treatment. Although such a case as this is unmistakable, it may, when complicated, lead to difficulty of diagnosis. If an attack of acute tonsillitis, an œdematous pharyngitis, a gummatous infiltration, or a malignant growth should occur, the appearance will then be very puzzling, and diagnosis probably impossible, until the case has been watched for some time. To Dr. Semon I am indebted for kindly allowing me to publish a case in point which lately presented itself at his clinique in the department for diseases of the throat, St. Thomas's Hospital.

E. O'D——, a married woman, aged forty-four, applied at the throat department complaining of pain in her throat and difficulty of swallowing, which had come on a few days previously. She also suffered from general *malaise*. It was with difficulty that she could open her mouth sufficiently to allow even an imperfect view of the fauces. The appearance then revealed was somewhat extraordinary. The whole of the left and the greater part of the right side of the isthmus faucium were occupied by a swelling, which so displaced the surrounding parts that it was with difficulty they could be made out. The swelling was continuous on the left with what looked like the left anterior pillar, and above with the soft palate. The root of the tongue was pushed down on the left side by the swelling. On the right side a small opening remained for the passage of food and air, but the posterior wall of the pharynx could not be seen. At the upper part of the swelling, and pushed over to the right of the middle line, was a small œdematous body, identified by its situation as the uvula. It consisted of a round mass about the size of a pea, suspended by a short thread-like pedicle from the upper part of the swelling. The swelling did not fluctuate, and was not very sensitive to touch. No enlargement of glands was to be detected in the neck. While from the symptoms one had expected to find on examination the appearances of an ordinary tonsillitis, what was seen was very different. The swelling, whatever it was, seemed to be one not confined to the tonsil, but involving also the soft palate and probably the posterior wall of the pharynx; the appearance, in fact, was that of a malignant growth or an infiltrating gummatous deposit.

The history of the patient was that she had suffered from sore-throat off and on for twenty-five years. She had been married nineteen years, and had had five children and two miscarriages. The children were said to be healthy. It appeared that she had applied at the throat department five months previously, but had only come once. On reference to the former notes of the case, it was found that the appearance at that time had been almost precisely the same. Dr. Semon then had left the diagnosis *in suspenso*, and had put down "acute tonsillitis (?); malignant disease (?); syphilis (?)." As to what had been the condition in the interval we were left completely in the dark. We had only the patient's word for it that she had been comparatively well in the meantime. I may add that there were no signs of choroiditis on ophthalmoscopic examination. The diagnosis was left once more doubtful.

The patient was ordered to take ten grains of iodide of potassium, along with a saline aperient, thrice a day, and two grains of guaiacum, in the form of a lozenge, every two hours. She was strictly enjoined to return in a week. She did return, and happily the mystery was solved. The swelling had greatly subsided and a good view could be obtained. It was at once seen that the case was one of syphilitic pharyngeal stenosis, which had been complicated with an acute tonsillitis. The soft palate had formed adhesions to the posterior wall of the pharynx everywhere, except a little to the right of the middle line, where there was a small opening leading to the naso-pharynx and admitting the passage of a small probe. The swelling evidently was seated in the left tonsil, which, in consequence of the adhesions, was so abnormally situated as to appear to spring from the posterior wall of the pharynx, as well as to be continuous with the left anterior pillar of the fauces. The remains of the uvula presented the same appearance as on the previous attendance, except that the œdema had subsided. The character of the attack, its rapid course, and its tendency to recur left no doubt that it had been acute tonsillitis. The patient remained under observation a few weeks, and then ceased attending. It was elicited by cross-examination that twenty-five years ago she had had what was probably secondary syphilis, having been in hospital at Tralee with a general eruption over the body, and having then been treated with medicine which made the gums sore. The case was thus a very interesting one, and from its rarity and temporary obscurity is worth recording.

A GENEROUS and ungrudging manner of conducting insurance business deserves to be noticed. The Law Fire Insurance Society has, we learn, just awarded a gratuity of £300 in alleviation of a loss by fire sustained by a medical man who practises on the Continent, and who had omitted to keep up the payment of the premium on his insurance for £500, in respect of some stored furniture, which was destroyed by fire eight months after the last payment.

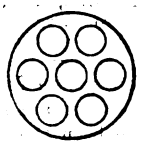
SOME SUICIDAL OR OTHER CEPHALIC INJURIES I HAVE SEEN.

BY BRIGADE-SURGEON W. CURRAN,
ARMY MEDICAL DEPARTMENT, RETIRED.

(*Concluded from page 581.*)

WHAT strikes one on reading the foregoing list is, first, the trivial or inconsequential character of the cause or provocation that led to some of these catastrophes; and, secondly, the absence of all reasonable motive for, as well as of any adequate allurement to, the perpetration of this crime. But then we are told that "of the direct inheritance of morbid qualities ..... suicide yields the most decided examples," and "it is both striking and startling to observe how strong the suicidal bent is apt to lie in those who have inherited it." Moreover, it is but fair to conclude that one or more of these men were the victims of involuntary impulse, and it is also fair to conclude that the reason of one of them gave way under the pressure of intolerable pain. We may be unable to recommend his example to the imitation of other like sufferers, or accept it, under similar circumstances ourselves. We can, however, do more. We can tell our pupils or subordinates that a few leeches seasonably applied in front of the tragus or behind the meatus externus will certainly relieve pain, and we may add that such an application might in this instance have saved a valuable life for the service of the State. "Human felicity," says Franklin, "is produced not so much by great pieces of good fortune that seldom happen, as by little advantages that occur every day," and the inculcation of lessons of this kind would be more profitable for the soldier and his surgeon than recondite dissertations about the course or the composition of bullets or secondhand rehearsals of the conjectural neology of German garrets.

Another reflection that suggests itself here has reference to that causeless or purposeless throwing away of health, and even of life, that so often characterises the conduct of the young soldier. But this fact or feature of his case is so common or so well known to his superiors as to cause them no particular alarm or surprise, and I have heard of one instance at least in which this suicidal tendency became endemic, through the force of example or imitation, in one well-ordered cavalry corps in the East. In this instance—to reproduce the *ipsissima verba* of my informant—"a troop sergeant-major who had contracted some debts which he could not repay blew out his brains in his own bungalow; another lay down on his cot just after talking quite rationally to a comrade, and immediately executed a similar movement; a third followed suit soon afterwards, and two others at more distant intervals, without making any sign of discomposure or premeditation. I have no reason," adds my friend, "to suppose that either of these men was insane," and I have myself elsewhere shown that the belief that all suicides are insane is, *au fond*, nothing better than an unreasoning superstition, or at best a popular fallacy.[1]



The bones of the skull were so shattered—smashed rather—in four of these cases as to be almost unreplaceable, but there was little or no disfigurement in the fifth, and this immunity my informant ascribed to the fact that the bullet had, in his case, certainly undergone fusion. It was diverted by its impact with the mastoid process into the brain, which it had mashed up in an extraordinary manner, and in which it was subsequently found in fragments. These cases are, I think, otherwise calculated to shed some light on that obscure question, the behaviour of lead in presence of bone. They also tend to shed some light on the lightning speed, as well as on the crushing powers, of this weapon or its contents; and I dwell upon them thus minutely—too minutely, perhaps—because they came under my own personal cognisance, or under the cognisance of persons on whose judgment and veracity I could entirely rely.

Another reflection that suggests itself here has reference to that relationship, as regards life and limb, which necessarily exists between shot and bullets in actual conflict. This question was raised some time since in another place, in connexion with the repressive measures of the late Mr. Forster in Ireland, and the weaker party—with whose national and other aspirations I am proud to say I heartily agree—*victrix causa Diis placint, sed victa Catoni*—strenuously maintained that the bullet was the speedier or more effectual medium of "interchange" of the two, and that it ought therefore be preferred. This conflict of opinion invests the question with a larger or more dramatic interest than it might otherwise command, and as the matter is still or in some measure *sub judice*, I introduce a somewhat diagrammatic sketch in elucidation of the point I wish to enforce. (Fig. 3.)

Now, if the candid reader will only compare these dots and the lacerations they produce with that little, almost undiscernible slit which he can make for himself on a corpse or on a carcase, he will at once see that, though the crash or the flash of the one may be much greater, the opening made by the other is and must be, *sua Natura*, as well as at close quarters, far more destructive and dangerous. Fired point-blank, shot will probably act as or like a bullet, and destroy life as effectually, but the result will be slower or more painful in the one instance than it is likely to be in the other; and if the victim of the former survives the shock or the hæmorrhage of the encounter, he will probably succumb after much pain and suffering to erysipelas or pyæmia. The question was, as I take it, one between slow death, with the probable mutilation of innocent spectators or casual outsiders thrown in, and the "happy despatch" of a speedy or painless death to one or more of the actual ringleaders of the riot, and there was an end of the matter.

The substitution, therefore, of buckshot for bullets, instead of being, as it was, I assume, considered by its advocates to be, a mitigation of punishment, was rather an enhancement and aggravation of it; and a description of an agrarian conflict of this kind that appeared in *The Times* of April 7th, 1882-83, confirms this. Detailing

FIG. 3.

Diagrammatic sketch of the appearance that is or might be produced by a charge of buckshot delivered at close quarters.

the incidents of this conflict, the writer says that "one of the men that was killed at Ballaghaderesn was shot in the arm, abdomen, leg, and heart. ..... One girl had her arm terribly lacerated, and fifteen others (i.e., it may be, casual lookers-on or outsiders) were wounded," and these were, I think, substantially the grounds on which objection was made to this substitution in and out of Parliament. Moreover, "a vessel which might possibly escape by yielding to the pressure of a bullet, has," as a well-known specialist points out, "scarcely any chance of avoiding division or destructive contusion when it is rained upon, as it were, by a small shower of shot from a fowling-piece," or from a policeman's rifle; and as to the other cavities or viscera of the body, their chances of escape from a bullet are much greater than they are where buckshot traverses the one or lodges in the other. It was, indeed, found, as a matter of fact, that when the Ashantees, or the Maories, or the Soudanese "managed to creep by stealth through the bush so as to be able to discharge their muskets at very close range, the wounds inflicted were sometimes of the severest kind, and in particular cases fatal." So speaks an expert whose authority on the point ought to admit of no question, and I should, I fancy, be only diminishing the weight and cogency of his arguments by any or such criticism or endorsement of my own as I might here offer or employ.[2]

Touching the lesions that result from accidents in the hunting-field or on race-courses, they have not, I think, received the attention their nature or numbers would seem to deserve or suggest. Nor do I pretend to be able to throw any very special light upon them. I have, however, seen two or more such casualties myself, and I have been brought into such close relationship with two or more others that I

[1] The Indian Medical Gazette, Nov. 1st, 1876.

[2] The experience obtained in this connexion, or since this was written, at Belfast, as that was reproduced by Mr. Foy in the Medical Press of Sept. 1st, appears to me to bear out and confirm these views.

may, I think, include them in this category or under this heading. I have also myself a depression of this kind in my vertex, which will, I know, accompany me to my grave, but from which, all the same, I have never suffered the slightest inconvenience, and I merely allude to it here to enable me to say that it is not your big falls that kill in these cases, but your "trivial rounds, your common tasks," when riders are returning home from the race or the chase, as the case may be, and their steeds are either jaded or off their guard. The former are either discussing the events of the day, or it may be the affairs of the nation, or they are communing far away with their own thoughts; the latter are possibly dozing or thinking of their stables, and—a slip or a stumble will do the rest.[3]

This is not, we all know, the common impression. On the contrary, most people couple casualties of this kind with a broken neck or other such terrible injury as can only be produced by a racing pace or a fall off a runaway horse; but some of our worse accidents have happened under situations of an entirely opposite character, and anyhow a mishap that has proved fatal to a great king[4] as well as to a great statesman, and also later still to a very distinguished and successful bishop, deserves some more attention at our hands than it has hitherto received. Post-mortems are notoriously the exception in such cases, and county coroners are more anxious to save the rates than solve nice points of diagnosis or pathology. These considerations induce me to take up the subject in this place or in this connexion, and the difficulties I have had to encounter in my search for authentic particulars in point must be my excuse for the incompleteness or other imperfections of the record subjoined below.

Many years ago—so many, indeed, are they that I am almost afraid to count them,—as I was travelling by one of the Bian's jingles[5] towards the capital of my native county in the south of Ireland, a wedding party approached us from a farmhouse on the right. Observing that they were in a somewhat hilarious, if it was not an actually aggressive, mood, our careful driver put on "a bit of a spurt," as he called it, in order to pass them; but they were not to be shaken off in that way, and urging on their steeds, in their turn, they emerged just in front of us on "the 'ard 'igh road." They then ranged themselves into line three-a-breast, and started off in a kind of racing gallop before us. One of them—an elderly man, who evidently carried more liquor on board than was good for him, and who, to show his youthful agility, stood up like a post in his stirrups—was soon seen to sway uneasily in his seat from side to side. He next bent forward on his horse's neck for a moment or two, and then toppled over head foremost on his unprotected cranium. I knew nothing of surgery or of any other science or art in those days, but I knew enough to feel that his hours on this earth were numbered (for we could all hear the thud or see the doubling up), and feeling that we could be of no use to him while we were rather behindtime than otherwise, we resumed our route and soon lost sight of him and his party.

This case made a great impression on me at the time, and this impression was enhanced by the occurrence several years subsequently of a somewhat similar catastrophe within the area of my own family. The subject of it, an elderly man, who had indulged one day more freely, as well as *more suo*, at a race meeting, than propriety would commend, was returning in the evening to his own house when the horse that drew his gig stopped suddenly before his gate, and threw him out on his head over the splash-board. He was taken up insensible and carried into his house, and my late brother (Dr. James Curran of Youghal) was sent for. Some two or three hours must have elapsed ere he appeared on the scene, and meanwhile our patient's appearance was so natural—nay, so life-like—that his friends and family thought he would soon "come round." This was not to be, however, for he had actually expired at the time of the fall, and my brother more than once assured me that his cervical vertebra had undergone no change of any kind. What the precise lesion was could not be ascertained, as the family objected to any disturbance of the remains, and I have often since thought that death resulted in his case from nervous shock, and consequent paralysis or suspension of the heart's action.

The third case that came under my cognizance occurred on the Killarney racecourse, and the body was subsequently conveyed for inquest purposes to the workhouse in which I then resided. I saw and examined it there the same evening and satisfied myself that the spinal column had given way in the neck. I asked the master of the house, who accompanied me, for permission to cut down upon and ascertain the extent or precise nature of this injury. I might as well have asked him for permission to burn down the house itself and all its inmates. His consternation bordered on collapse. He stared at me in such a state of wild amaze or bewilderment as seemed to imply that he had either lost the power of speech himself or that I had suddenly become insane; and yet he was by no means a discourteous or unintelligent man; on the contrary, he was superior to his position; but his bread was at stake, and he well knew that his guardians and neighbours regarded such a procedure with horror and disgust. He assured me afterwards that compliance with my request would probably involve the loss of his place, and it was here that I heard for the first time the curious distinction which my poorer countrymen draw between the phrase "kilt" and "kilt entirely." Anyhow we—self and a local *confrère*—were asked a score of times at least as we returned from the scene of the disaster to the grand stand, if the victim of it was "kilt." On being gravely assured that he was, we were then asked. "Eh! then, is he kilt entirely, sir?" and when our response was again in the affirmative, there was a deep sigh from the heart as well as a deeper expression of gloom and sympathy on the faces of our interrogators.

As I hunted as a boy with the hounds of that famous hunter and thorough sportsman, the late—but one, I think—Marquis of Waterford, I may, I presume, include his name in this series. I was, however, abroad at the time, and, having omitted to take any note of the occurrence, was obliged to trust to others for the few items respecting it I am now about to give. Dr. Martin of Portlaw's name is, however, so well known as to be itself a sufficient warranty for the accuracy of any or such account of it as he may give, and it is to him that I and my readers are indebted for the following narrative. "The Marquis was," says Dr. Martin, "going down a small ditch with a drain at the bottom of it, the edge of which gave way under its feet, and the horse going out on its nose, he (the rider) fell forward on its neck. When the horse raised its hinder feet, to extricate itself, the Marquis went out on the top of his head, and did not speak or move again. As his weight at the time was sixteen stone, "the atlas was most probably dislocated; but there was no post-mortem examination, and the medical man who saw him five minutes after the fall pronounced him dead."[6]

As was the appearance of the face of my relative so was it also with that of the noble Marquis. Though six hours had passed before the body was seen by Dr. Martin, yet did "the blood remain so fluid as to give rise to such a blush over his face as actually simulated life," and I am quite unable to explain these appearances. He even admits that it required some cautious manipulation as well as deliberation on his part ere he could finally pronounce him dead, and I cannot accept mere flexibility of the neck as distinctive of a dislocation. The neck in man is, and must necessarily be, possessed of much flexibility; this flexibility would be increased under the conditions here indicated,

[3] I made the following note of an occurrence of this kind that took place when I served in Pembrokeshire from '58 to '61 or so. It speaks for itself, and runs as follows:—"A Captain Philips of Haverfordwest was, while riding unconcernedly over a low fence one afternoon, as he returned from a day's sport with the local hounds, thrown, through a slip on the part of his horse, on his head, and sustained a dislocation of one of his cervical vertebræ. He died soon afterwards." And the curious thing about this painful accident is this: he was actually cautioning his companion against the very mishap that proved fatal to himself at the very time the accident happened. *Sic transit gloria mundi.*

[4] William was not killed by the fall itself, as is so often erroneously thought; he simply succumbed to the effects of it afterwards. Describing the destruction of Mantes, and the king's delight at the sight of the burning city, Mr. Freeman says (Norman Conquest, vol. iv., p. 703) that "at that moment his horse stumbled, and.....the body of the bulky king was thrown forward against the tallíron of his saddle. He kept his seat, but the pain of the blow was such that his eagerness was quenched, and he ordered a retreat to be sounded. He survived this 'death wound' several weeks, but *consulti medici inspectione urinæ certam mortem prædixere*, and there was probably a rupture of the bladder with its usual consequences or complications—extravasation of urine, peritonitis, &c."

[5] Bian is simply an abridgment of Bianconi, the founder, as everyone knows, of these "jingles," or outside cars, in the south of Ireland. The peasantry invariably speak of him thus.

[6] "Old James Cusack told me at the time," says my courteous correspondent, Dr. Martin, "that he had seen two such cases as the Marquis's, and that he had made post-mortem examinations in both. He found that the odontoid process of the axis was dislocated in both these subjects, while the ring of the second vertebra was fractured in one of them at least; and it is much to be regretted that no similar search was made in the case of the Marquis."

and the common belief that the neck is in such cases *always* broken or dislocated is nothing more nor less, in my humble opinion, than a popular fallacy or an ignorant assumption.

Having thus disposed of what I may, I think, venture, with a very pardonable stretch of imagination, to call my own personal share of this experience, I will now turn to another phase of the question and endeavour to show that that, too, tells the same, or at least a very similar, story. This story is not, however, conclusive, for so infrequent are skilled examinations instituted in these cases, or so anxious are coroners and juries to ascribe them to "accident," that nothing tangible transpires from such inquiries, and lay writers are only too apt to follow suit. They invariably then ascribe such deaths to a broken neck, or they give such descriptions of them as are irreconcilable one with the other, or as may admit of any interpretation the casual reader may wish to put upon them.

Thus, to go no further, describing the then recent deaths of two huntsmen of his acquaintance, a writer in *Baily's Magazine* for June, 1876, says that "when one of these (Jem Morgan) retired his son took his place, and old Jem continued to hunt with the pack occasionally. One day on a frosty morning, as he was trotting to cover, on the side of the road his horse slipped up and gave him a very severe fall. However, he rode on to the meet and actually turned the hounds to his son, but feeling very bad (*sic*) he rode to a farmhouse, got off, laid down on a sofa, and died immediately, *his neck being broken*." Had this been so, he could not, I opine, have survived his fall so long or acted otherwise as he did, and I merely italicise this opinion to enable me to point out its inherent improbability, and point out also, at the same time, the inadequacy of the grounds on which these casualties are so frequently classified.

The story is told somewhat differently by another leading organ of the sporting fraternity, whose decease this same fraternity has had recently to deplore. Speaking of it at the time in somewhat similar terms to those employed above, this journal says that "it—Jem Morgan's death—was occasioned by his horse slipping up and seriously injuring him. It was thought," continues our correspondent, "that he must have got kicked in the back, and though able to ride for an hour after, he gradually became quite feeble, and died soon after at a friend's house on the sofa without a struggle. He was between seventy and eighty years of age," and a verdict of "Accidental death" was, the writer adds, returned, on the evidence of the medical man who inspected the remains. This statement entirely confirms, I think, the impression I have so long entertained of these casualties. It further goes to show the unreliability of the ephemeral descriptions we are so accustomed to of a morning in our papers. I believe that nothing more than a slight effusion into the ventricles of the brain or into the membranes of the cord, would have met the eye of the anatomist who examined these remains. For the effects of shock are not always obvious to the senses, and as to that capillary stasis or nervous relaxation that so often characterises the end of life—they sometimes elude the ken of even the keenest microscopist.

When, as in a recent instance, the horse falls, "throwing his rider on the back of his head and crushing his body by rolling on him," there can, of course, be no doubt as to the diagnosis or the prognosis either, but this kind of crushing is not common, and we more frequently find that the "stunning" that is produced—to give it its popular designation—by horse and other falls of this kind is either momentary or so fugitive as to leave no serious trace of injury behind it. There can, on the other hand, be no doubt that, as the law of the strongest so forcibly enjoins, the neck must be either broken or dislocated under several of the contingencies here contemplated, and this is, too, I think, the experience of hospital and other consulting surgeons.

Thus, courteously answering a question on the point I put to him, Mr. Reginald Harrison assures me that he has seen two such cases, and he classifies the lesions found on these as follows:—"The death of one of them resulted from a fracture which involved the four upper cervical vertebræ; the death of the other resulted from a rupture of the transverse ligament of the atlas, coupled with which was a displacement between this bone and the axis"; and he thinks that "the deaths that occur a few hours after the accident are generally traceable to fractures of the base of the skull." That is so, doubtless, in many of these cases, but it is certainly not so in all, or even in a majority of them, and I have long been of opinion that this particular fracture is just as big a bogey in this connexion, as well as at coroners' inquests and in medical parlance generally, as is its bigger brother the "break-neck" theory or assumption of the penny-a-liner of the period, or of his equally credulous or unreasoning audience, the outside public.

Finally, and as regards some of the fatal accidents that have occurred in connexion with the "Grand National" or other race at Aintree—where I have myself often been,—I am enabled to give, on the authority of an old jockey and weigher of that institution, the few following authentic particulars: This now famous "meet" was instituted in 1827, and several riders have since then paid the penalty of their daring with the forfeit of their lives. Among these were Doyle, Edwards, McDonald, Stevens, and Wyn, and how many others were maimed or injured there I am unable to say. "Two of the above (Doyle and Stevens) died at the gorse fence in front of the big water-jump of broken necks. Edwards died of concussion of the brain three days after his fall at the 'bushes'; and McDonald's death, which took place, I think, over the 'flat,' and which was the latest—let us hope it may be the last—of the series, resulted from a crushing as well as a kicking he sustained on the ground through a 'cannon' which took place while they were racing at full speed between his own and another rider's 'mount.'"

As to the last-named jockey, young Wyn, a son of the well-known Irish steeple-chase rider, Denny Wyn, I find from my own notes that he was killed at the brook there in 1862. His horse, named O'Connell, cannoned against another while they were both in the air, or rather, as they were both alighting from their spring into that unstable element, and fell on him. This fall produced a fracture of the sternum, and such an amount of shock—possibly also of hæmorrhage—as led to immediate unconsciousness and speedy death; and though I have by me notes of several other cases of this kind, they happened so far away, or are otherwise so ill-described, as to be unsuited for reproduction here. I therefore bring this little essay to a close, with the hope that, though I may not have succeeded in shedding any very new light on the matters it discusses, I may have contributed, in however small a degree, to dissipate some of the obscurities that surround them. Should this prove to be so—should, in other words, the outcome of my own and of some other more competent observer's personal or professional gleanings be such as to lessen prejudices, and remove misrepresentation or illusion—the object I had in view in undertaking it will be more than realised.

Bibliography.—As the length of this paper precludes any detailed corroborations of its facts or statements by means of foot-notes, while the readers of it may wish to know something of the authorities on which these are based, I subjoin a list, in alphabetical order, of the writers—periodical or otherwise—to whom more or less reference has been made in it:—H. C. Bastian, M.D.: "The Brain as an Organ of Mind," p. 29. *Baily's Magazine* for June 1876, p. 38. *Bell's Life* for Feb. 2nd, 1862. *British Medical Journal* for Oct. 23rd, 1880, p. 655; see also, in the same direction, *ibid.* for April 16th, pp. 593-6. Drinkwater: "A History of the Siege of Gibraltar," p. 73. Fox: "A Journal or Historical Account of the Life of George Fox," London, 1694, vol. ii., pp. 151-2. Franklin: "Autobiography," p. 121. *Fraser's Magazine* for Feb. 1874, pp. 311-12. THE LANCET for Dec. 17th and 24th, 1881—Prof. Longmore: "Gunshot Injuries," pp. 72, 89, 104, 135, &c. H. Maudsley, M.D.: *Fortnightly Review* for 1886, p. 654. *Cork Herald, Morning Post, Standard, Times, Vanity Fair, Warrington Guardian*, &c. S. W. Rowley, M.D.: "Schola Medica," p. 9. Shakespear: "Wild Sports in India." Wilson: "The Abode of Snow," in *Macmillan's Magazine* for Nov. 6th, 1874, pp. 564-9. "The Supplementary Despatches of Wellington," vol. i., p. 162. Stanley: "The Dark Continent," vol. ii., p. 115.

THE PREVENTION OF HYDROPHOBIA.—A society has just been formed with the title of "The Society for the Prevention of Hydrophobia and the Reform of the Dog Laws." The objects of the society are to extend the regulations relating to the muzzling of dogs all over the United Kingdom, and to make them more stringent as occasion requires, to advocate a graduated dog-tax, and to promote efforts to obtain a more speedy legal redress for dog nuisances than at present exists.

TWO SUCCESSFUL CASES OF GASTROSTOMY;

ONE COMPLICATED BY TRACHEOTOMY.

BY C. STONHAM, F.R.C.S. ENG.,
SENIOR ASSISTANT-SURGEON AND PATHOLOGIST TO THE CANCER HOSPITAL, BROMPTON.

CASE 1.—Richard A——, aged thirty-seven, applied for relief on Jan. 15th, 1885, with the following history. Twelve months before he had "a cold in the head and sore-throat," and the doctor told him the throat was ulcerated, and "burnt it" on three or four occasions, with temporary benefit. Four months later the throat became worse, and he was admitted into St. George's Hospital and treated as an in-patient for fourteen days; nothing was done locally, but he says he had medicine containing "iodide of potassium," which did him no good. The throat troubles gradually increased, and three months ago he noticed that speech became thick and difficult, and there was slight dysphagia. Fourteen years ago he had a chancre, followed by a rash but no sore-throat. He thinks the disease may be due to smoking.

Present State.—Jan. 15th: There is an extensively ulcerated epitheliomatous mass involving the right posterior part of the tongue and floor of the mouth, the right tonsil and pillars of the fauces, with the right half of the pharynx, and extending downwards as far as the epiglottis. The glands in the neck are a good deal enlarged. The growth is extremely sensitive, and the patient cannot bear it to be even lightly touched, the examination with the finger causing excruciating pain.

On Feb. 5th the growth was rapidly extending in all directions, and only liquid food could be taken on account of the great severity of the pain when anything passed over the ulcerated surface. In the hope of alleviating this the lower molars were extracted. From this time he very rapidly grew weaker, and, the growth extending, became very anxious to have something done to relieve him and to enable him to take sufficient food. Accordingly, I proposed gastrostomy to him, explaining the nature and risks of the operation. He decided to have it performed, and on Feb. 17th the first stage was completed under strict antiseptic precautions. An incision was made parallel with the margins of the seventh, eighth, and ninth ribs, and a finger's breadth internal to them. The structures in the abdominal wall were successively divided, and the great curvature of the stomach immediately presented in the wound, and was united to the peritoneum and skin by fourteen silk sutures, which only passed through the muscular and peritoneal coats of the organ. The great omentum was the only other structure seen. There was no sickness during or after the operation.

Feb. 18th: Patient passed a comfortable night, and has been free from pain. The tongue is very dry, but is moistened with glycerine and water in equal parts. The temperature and pulse are normal. He has a nutrient enema every two hours, consisting of two ounces of strong beef-tea, ten grains of pepsine, and twenty grains of pancreatine. These have all been retained.—20th: Feels quite well, and the nutrient enemata satisfy him. They now contain yelk of egg, and are all pancreatised.—22nd: The temperature and pulse have been quite normal since the operation, and the bowels have acted properly. He has only experienced inconvenience from the great dryness of the tongue. To-day he feels a little hungry. The dressing was removed, and the stomach was seen to be coated with a thick layer of vascularised lymph. There is no tenderness round the wound, but a little redness at the points of suture. A small hole was made in the stomach with a small scalpel, and through this a piece of indiarubber tubing about the size of a No. 10 English catheter was inserted. There was no escape of fluid from the stomach, nor did any of the warm milk, which was poured in, return. The abdomen round the wound was well oiled and powdered with chalk, and the tube (clamped) was retained in its place by a strip of plaster and thread.—23rd: The enemata have been discontinued, and all food has been given by the stomach. The rubber tube has been replaced by a vulcanite self-retaining female catheter. Altogether he has taken about three pints of beef-tea and milk, and has rinsed his mouth out with milk on account of the dryness of the tongue. The pain in the throat is very much better since the operation, and he expresses himself as being very pleased with the result.—25th: All the sutures were removed.—27th: Got up to-day for the first time. Minced meat and biscuit powder have been added to the diet.—March 3rd: There is a very marked improvement in the general condition of the patient; he looks more cheerful, and is now almost free from pain, and the growth has certainly not spread with anything like its former rapidity, and its surface looks less sloughy and red. The diet consists of milk, eggs, minced meat, biscuit-powder, arrowroot, and beef-tea, and he also takes three ounces of port wine by the mouth without experiencing any pain. He is quite able to feed himself, and smokes two or three pipes a day; this he had not been able to do for a long time before on account of the pain it caused. The skin round the fistula is quite healthy, and there has been no excoriation, owing to the free use of powdered chalk.—24th: Has gained a pound and a quarter in weight since the last note.

This man left the hospital in April and went into the country, and I did not have an opportunity of seeing him again, but I heard that he died in the infirmary on June 20th from exhaustion consequent on the disease, but that he was quite comfortable until the last. The doctor of the infirmary did not make any post-mortem examination, and as I did not hear of the death until a week after I could not do so.

CASE 2.—Mary D——, aged forty-seven, was admitted under my care on Nov. 20th, 1885, with the following history. Two and a half years ago she had a severe cold in the head, which "completely destroyed taste and smell, and these have never quite returned." This was followed by a swelling on the left side of the neck, just below and behind the ear, which gradually grew until it attained the size of a hen's egg, but never gave any pain. Some months later there was a discharge of blood and matter into the throat, accompanied by a diminution in the size of the swelling. This occurred about each fortnight. Two months ago a swelling appeared in the submaxillary region, and has gradually grown. For five years she has suffered from pharyngeal and laryngeal catarrh. There is a good family history, and no suspicion of cancer.

On admission, there was a large, slightly movable tumour on the left side of the neck, extending downwards from the mastoid process about 2 in.; behind, it reached the posterior edge of the sterno-mastoid. Below and behind this many small glands could be felt. In the submaxillary region there was a hard immovable swelling, separated from the posterior one by a sulcus. The tumour was of large size, and had pushed the hyoid bone and larynx a little to the right. The submaxillary glands on the right side were enlarged. In the mouth (which could only be opened half an inch, although lateral movement was very little impaired) an indurated swelling, extensively ulcerated on the surface, could be felt, implicating the posterior third of the left half of the tongue and extending to the anterior pillar of the fauces, the tonsil, and down the left side of the pharynx. The growth extended across the middle line, and on examination under chloroform it was found to be impossible to reach the lower border with the finger. The passage from the mouth to the pharynx was only just large enough to admit the forefinger. Deglutition of solids was impossible, but liquids could be swallowed in small quantities. Respiration was somewhat laboured, and the patient was suffering severely from inanition, being very much emaciated. She was very anxious to have something done to relieve her, and, after consulting with her friends, decided to have gastrostomy performed.

On Nov. 24th the first stage was performed, with the same precautions as in the previous case. The edge of the liver presented in the wound, and had to be pulled to one side. Fourteen silk sutures were used to attach the stomach to the wall, the parietal peritoneum having previously been sewn to the skin by a continuous catgut suture. At an early stage of the operation it was found necessary to perform tracheotomy, owing to the dyspnœa and inability to open the mouth.

Nov. 25th: Passed a comfortable night, although the trachea tube caused some irritation. The temperature is normal, and she feels well. Nutrient enemata have been used, as in the other cases.—26th: The tube in the trachea was removed in the night at the patient's request, but had to be replaced in two hours.—27th: The greater part of the enemata given to-day were returned. She has had six hours' sleep after a hypodermic injection of a quarter of a grain of morphia, and feels much better for it. The enemata have been retained. The dressing was removed at

Digitized by Google

8 P.M., and the wound was found quite healthy, the stomach being covered with a thick layer of lymph. The viscus was opened, as in the former case, and a tube inserted, and about an ounce and a half of warm milk injected.—Dec. 1st: The patient has been quite well since the operation, and has had plenty of food by the stomach. The trachea tube is still retained, as she is very much more comfortable with it in. All the sutures were removed to-day, and the patient has had meat for the first time.—4th: Got up to-day for a little while. Is feeling very much better than she did before the operation was performed.—7th: The tracheotomy tube has been left out to-day at the patient's own request, although there is marked dyspnœa without it. She is much stronger than before the operation and has visibly gained flesh. She expresses herself as very pleased with the result, as it has given her so much relief.

This patient died on Dec. 30th, but did not suffer much, a little dyspnœa being the only difficulty. For the following notes of the post-mortem examination, which was made on Dec. 31st, I am indebted to Mr. Elam, the surgical registrar:—Rigor mortis passing off. Body greatly emaciated. The left side of the base of the tongue and left side of the fauces infiltrated with new growth, which is indurated and ulcerating. The whole of the anterior and part of the lateral walls of the pharynx are studded over with indurated projections, pale in colour, and varying in size up to that of a haricot bean; these were not ulcerated, and ceased suddenly near the œsophageal opening. In an upward direction there was a hard growth on the left side extending to and adherent to the bones of the base of the skull. The growth is hard and pale grey in colour. Growing beneath the angle of the jaw into the submaxillary region, and apparently connected with the preceding, was another hard mass, rounded and well-circumscribed, about the size of an orange. The glands behind the sterno-mastoid were enlarged, and many of them broken down in the interior. The larynx was slightly œdematous. There was no new growth in the lungs, but the left one was adherent to the diaphragm. On opening the abdominal cavity there was very little fat to be seen in the wall or in the great omentum. The stomach was contracted to about half the normal size, and contained a little dark fluid. The fistulous opening was at the great curvature. The liver was enlarged and soft, and on the upper surface of the left lobe, opposite the gastrostomy wound, it was covered with lymph, the result of local peritonitis. The other organs were healthy.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

CASE OF SPINA BIFIDA SUCCESSFULLY TREATED BY OPERATION.

BY JOHN KELLOCK BARTON, F.R.C.S.I.,
SENIOR SURGEON TO THE ADELAIDE HOSPITAL, DUBLIN.

INASMUCH as the treatment of spina bifida is still unsettled, any case in which a successful operation has been performed is worthy of record. So, very briefly, I will state the particulars of the following case which has been lately under my care in the Adelaide Hospital.

On July 9th, Susan H——, an infant two weeks old, was brought to the hospital by her mother, who had been attended in her confinement by Mr. Hamilton, a pupil of the Adelaide. He had noticed at the time of birth a tumour in the lumbar region, about the size of a small walnut, of a dark purple-red colour. This tumour steadily increased in size, and at the time I made my first examination was the size of a small egg, or might more accurately be likened to the half of a small orange, the convex part projecting, the flat or cut surface of the orange attached to the lumbar spine. The surface of this tumour was occupied by a greyish sloughy ulceration, while the sides were of a deep purplish-red colour. Fluctuation was very obscure, but pressure certainly diminished the bulk of the tumour, which regained its original size quickly when the pressure was removed. The nature of the tumour, so far as that it was a spina bifida, was pretty clear; but to make this more certain I thrust a fine hypodermic needle into it, and drew out a few drops of a perfectly colourless serum. The question of its being a spina bifida was now established, but the further and more difficult one of whether the spinal cord formed any portion of its contents remained doubtful. The fact that no paralysis existed, either of the sphincters or lower limbs, induced me to believe that this was a meningocele, and not a myelocele; but the facts of its low position and of its purple and ulcerated surface are held by authors[1] as leading to an opposite conclusion, and the result proves that the freedom from paralysis is of more diagnostic value in deciding this important point than is either the situation or the character of the tumour.

Next day, I performed the following operation, the infant being under the influence of chloroform. I cut an elliptic piece out of the centre of the tumour, thus removing all the sloughy central portion; the wall was thick, internally smooth and white, and with numerous small nerves passing into the portion removed, which were of course cut across. Very little time was lost in stopping all bleeding, which was insignificant, and then drawing together the thick purple flaps left on either side by a double row of sutures. Careful antiseptic precautions were observed, and the dressing consisted, first of all, of a dusting with iodoform, then a covering of corrosive gauze (1 in 400), secured well at its edges and round the body with an antiseptic gauze bandage. There was no elevation of temperature, and union was complete and firm in a week. No signs of any disturbance of the nervous system followed.

In ten days the infant was discharged cured. I questioned the mother as to any loss of power in the limbs, of which the child has free use. The situation of the tumour is now occupied by a puckered purple oblong swelling, about one-sixth of the size of the tumour which I operated upon, and I have no doubt further contraction will go steadily on for some time.

P.S.—Since this report was written I have received information of the death of the child in a fit of convulsions. No doubt the union of the operation-wound was complete, but the convulsive attack came on too soon after the operation for us to dissociate the one from the other.

Dublin.

ON A CASE OF ABDOMINAL PREGNANCY.

TERMINATION BY ULCERATION INTO RECTUM; RECOVERY.

BY RALPH BROWNE, L.R.C.P., M.R.C.S.

E. J ——, aged forty. Has had ten children, the youngest being five years old. Has not had any miscarriages, and gives no history of previous disorders in the organs of gestation. She had last menstruated in November, 1884 (seventeen months previously). She believes herself to have been in her usual good health, and does not remember to have had any fright about that time. In the course of a month or so she began to suffer from metrorrhagia, which continued, and led her to seek advice.

On examination, a tumour was found upon the left side of the abdomen. From its position and feeling, it was diagnosed as ovarian, and it was also suggested to the patient that she was pregnant. The metrorrhagia continued more or less, until in September, 1885, or at what would be about the full period of pregnancy, a pseudo-labour took place, and an effort at lactation appeared in the breasts. About this time the patient began to notice that the tumour seemed smaller, but complained of loss of appetite, general ill-health, and pain and irregularity in the action of the bowels. This state of things continued until April last, or seven months after the pseudo-labour, when she was taken with violent forcing pains in the body and lower bowel, and offensive diarrhœa, in the course of which some fœtal bones were passed. Examination of the rectum disclosed the presence of the remainder of the fœtus. A hand was introduced into the bowel, the fœtal head crushed as far as possible with the fingers, and its fragments and other bones removed. The diarrhœa, and the occasional passage of a remaining bone, continued for a few days, gradually became less offensive, and then ceased. Within a fortnight the patient was able to leave her bed, and has since made an uninterrupted recovery.

From the frontal bones removed entire, each measuring an inch and a half by an inch and three-quarters, and from the

[1] Dictionary of Practical Surgery, vol. ii., p. 470.

Digitized by Google

other cranial bones fitted together, the bi-parietal diameter was computed to be three inches. All the bones had the normal amount of ossification of a full-time fœtus.

Points of interest in this case are: 1. The difficulty of diagnosis, though, looking back now, nothing can be clearer than the sequence of events. 2. The maturity and perfect formation at which the fœtus arrived. 3. The means taken by Nature to remedy her error, and which resulted in perfect recovery.

King's Lynn.

A SUGGESTED ALTERATION IN THE COMPOUND LIQUORICE POWDER.

By MARTIN OXLEY, M.D.

HAVING found that the above preparation produced very severe griping in many instances where I had ordered it, the griping being particularly severe in some of my younger patients, I have ordered the following formula for some time past, in which anise fruit is substituted instead of the fennel and one-fourth part of ginger is added. The altered formula runs thus—senna and liquorice-root, of each 2 parts; anise fruit and sulphur, of each 1 part; sugar, 5½ parts; ginger, ¼ part. This altered preparation is quite as satisfactory in its laxative properties, is less liable to gripe, and is as pleasant to take as the official powder, and I would suggest its trial in cases where the powder as now prepared produces the disagreeable effects to which I have referred.

Liverpool.

DOUBLE FRACTURE OF THE UPPER LIMB BY INDIRECT VIOLENCE.

By ALEX. FOULERTON, M.R.C.S., L.R.C.P.,
RESIDENT MEDICAL OFFICER, ROYAL ISLE OF WIGHT INFIRMARY.

THE following is noteworthy as a somewhat curious result of indirect violence applied to the upper extremity.

A child, aged nineteen months, was being led along the street by his mother, who was holding his right hand. The child stumbled, fell with a jerk, and was dragged up again—roughly, probably—by his mother, who, however, never left go of his hand. She then noticed that the boy's arm was quite powerless, and hung loosely by his side. Shortly afterwards the child was brought to the infirmary, where it was found that two fractures had occurred, one through the upper epiphysial line of the right radius, the other at the junction of the middle with the acromial third of the right clavicle. One would certainly have expected dislocation rather than fracture as the result of such an accident occurring in so young a child, and I must confess I am unable to offer any exact explanation as to the mechanics of the lesion.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum allorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

LONDON HOSPITAL.

A CASE OF PRIMARY CANCER OF THE VAGINA, LEADING TO RETENTION OF URINE; NECROPSY; REMARKS.

(Under the care of Dr. HERMAN.)

IT is not usual for epithelioma (for such the disease in this case probably was) of the vagina to produce retention of urine; in the majority of instances the ulcerative process extends, and by the establishment of a fistulous communication with the bladder, causes incontinence. The difficulty met with by the surgeon in alleviating the effects of this may occasion him much anxiety, whilst it is a serious addition to the suffering caused by the disease. There is, however, a great difference between such opening and that produced and controlled by the surgeon; the opening in this case appears to have relieved the retention, and also the pain, which was produced both by the passage of a catheter and the flow of urine over the ulcerated surface.

M. S——, aged forty-one, married, was admitted into Victor ward on Oct. 10th, 1883. She began to menstruate at the age of eleven, and after the age of twelve was always regular except during pregnancy, the flow lasting four or five days, being moderate in quantity and without pain. She was married at the age of sixteen, and in the first fourteen years of married life gave birth to eleven children, two of the pregnancies being with twins. She also had two miscarriages. Of the children only two are now living. Thirteen years ago, during one of her pregnancies, she had some kind of fit. With this exception she has always had good health. For the last ten years she has been employed as a monthly nurse. The patient thought herself well until seven months ago; then, while exerting herself more than usual, she suddenly felt a sharp pain in the lower part of the abdomen, like a sprain, and on subsequently sitting down she felt a "bearing-down" pain. This has continued ever since. A little later in the day she had a "flooding," losing, she considered, a pint or two of blood. This made her feel extremely faint. Hæmorrhage continued for about three days, and then was replaced by a white vaginal discharge. A discharge has been present ever since, but about six weeks before admission it became yellow and offensive. For the last six weeks she has suffered from scalding pain during and after micturition. For the same time the glands in the left groin have been enlarged and hard, but she has not had any pain in them. A day or two before admission she discovered similar enlargements in the right groin. Throughout the past seven months she has been progresively losing flesh. The day before admission she found herself for the first time unable to pass urine. This inability continuing, she came to the hospital, where the urine was drawn off and the patient admitted.

Condition on admission.—The patient is much wasted. The glands in both groins are indurated and enlarged, the left being the larger and fixed. On vaginal examination the anterior wall of the vagina is much thickened, very hard, uneven, and ulcerated. The thickening is especially marked at the lower part, where the induration involves the meatus urinarius. There is an isolated hard lump in the left labium. The cervix uteri is healthy but there is a hard lump to the right of it. The urine is acid; sp. gr. 1010; no albumen, pus, or phosphatic deposit. No physical signs of disease elsewhere.

Oct. 26th.—The patient has passed urine naturally since admission, but is now again unable to do so. Dr. A. J. Richardson (resident accoucheur) tried to pass a catheter, but found the urethra so surrounded and blocked with new growth that he was unable to get the catheter through it. The patient was then put into a hot bath, and twenty minims of tincture of opium given. These measures had no effect, and therefore the bladder was aspirated through the vagina.

27th.—Under anæsthesia a catheter was passed, and left in the urethra for the next three days. It was then removed, and the patient was able to pass urine naturally.

Nov. 13th.—The patient again had retention of urine, which has been relieved by the catheter. The glands in the left groin have ulcerated, and the left labium is œdematous.

16th.—The patient continues unable to pass urine. The catheter can be passed, but its use causes extreme suffering to the patient. The bladder was therefore opened by an incision from the vagina, and a winged indiarubber tube put into the opening to keep it patent. After this had been done the patient was in comparative comfort. There is now slight œdema of the right thigh.

28th.—Delirious. The whole of the right leg is œdematous.

On Dec. 11th death occurred. The necropsy showed cancer of inguinal glands on both sides, those on the left ulcerated. Bladder contracted, capable of holding an ounce and a half of fluid. Cancer of anterior vaginal wall and urethra, extending along posterior wall of bladder. Kidneys sacculated, especially the right, which only weighed two ounces, left three ounces. Right ureter distended with urine. Right ovary cancerous, and the size of a walnut. Uterus not diseased. Secondary deposit in liver.

Remarks by Dr. HERMAN.—The case is an interesting example of a rare form of disease, and of a rare event in the history of that disease. Cancer of the uterus often extends

Digitized by Google

to the vagina, but primary cancer of the vagina is rare. When it occurs the posterior wall of the vagina is its usual seat—not the anterior, as in this case. It is also rare for cancerous growth to so block the urethra as to cause retention of urine; in the case now reported this complication occurred. There was mechanical obstruction to the flow of urine and the entry of the catheter, and the passage of the instrument caused such extreme suffering that the establishment of an artificial vesico-vaginal fistula proved an alternative preferable to repeated catheterisation.

BRISTOL GENERAL HOSPITAL.

EXCISION OF THE ELBOW-JOINT, WITH SUTURE OF THE OLECRANON TO THE SAWN END OF THE ULNA; REMARKS.

(Under the care of Mr. C. F. PICKERING.)

A. F——, aged fifteen, a strumous girl, had suffered from disease of the elbow-joint since June, 1885. In February, 1886, she was admitted into the hospital, and erasion of the joint was performed. The joint was at that time found to be in an advanced state of pulpy degeneration, but the cartilages were healthy. This operation was only partially successful in stopping the progress of the disease, and in the following July, as the arm was becoming stiff, it was thought advisable to excise the joint. This was done on July 8th, in the following manner. A longitudinal incision about three inches in length was made over the back of the joint, exposing the olecranon. The tip of this was then divided with a sharp chisel, and the joint was thus opened. The cartilages were found to have completely disappeared by ulceration, and the articulating surfaces of the bone were bare and in a carious state. The olecranon, with the triceps attached, was now turned up out of the way and the operation proceeded with in the usual manner. After the diseased ends of the bones had been removed, the tip of the olecranon was united by a strong wire suture to the sawn surface of the ulna. Drainage-tubes were inserted, and the wound sewn up. The operation was done under strict antiseptic precautions. The patient made a good recovery, the temperature remaining normal throughout.

Remarks by MR. PICKERING.—I hoped, by the union of the olecranon to the ulna, to greatly improve the movement of extension in the false joint, as the triceps in this way would be acting to greater advantage than in the usual mode of performing the operation, in which the principal attachment is cut away and the power of extension only depends on the muscular fibres inserted into the fibrous aponeurosis of the forearm. This case has so far been successful, as, though the time has not yet come for the arm to acquire perfect movement, the power of extension is good, and better than that of flexion; the latter has been delayed by the greatly wasted condition of the biceps. The tip of the olecranon has firmly united to the ulna below, and the wire has not been removed, as it is causing no irritation. Only the tip of the olecranon should be cut off, and it should be united subsequently to the ulna by very strong and thick wire, so as to hold it firmly.

CHESTER GENERAL INFIRMARY.

CASE OF HIP-JOINT DISEASE; RESECTION; AMPUTATION AT THE HIP-JOINT; RECOVERY.

(Under the care of Mr. J. TAYLOR.)

THE following notes are by Mr. W. Lees, house-surgeon.

Mary B——, aged eighteen, residing at Acrefair, Ruabon, was admitted on May 20th, 1885. The patient had never been strong, was of strumous appearance, and had suffered from repeated attacks of hæmoptysis. One sister died at nineteen years of age from hip-joint disease, and another sister suffers from chronic abscesses in the neck; the rest of the family are healthy. Her present illness began in February, 1885, when there was acute pain in the right knee, which was swollen and very tender to the touch. For this the joint was painted with tincture of iodine. In March following she was in bed for three weeks under medical treatment at home. In May, being much worse, she came to the Chester Infirmary.

On admission the knee and foot were considerably swollen; temperature 101°; pulse 100. The limb was put up on a back splint for four weeks. The patient now for the first time complained of pain in the right hip-joint, and for this an extension apparatus was applied. She had a severe cough, and also attacks of hæmoptysis and epistaxis; she had not been unwell since February, 1885. In July an abscess was noticed to be forming on the outer side of the hip. This remained stationary in size till January, 1886, when it increased rapidly. She was also getting weaker, and the temperature was of a very hectic character. On Jan. 19th the abscess was opened, under strict antiseptic precautions, by an incision three inches long, to the inner edge of the tensor vaginæ femoris: no diseased bone was felt; a drainage-tube was inserted, but was never shortened. She was very sick after the chloroform. After this the temperature fell to normal for twenty-eight days. From this period up to the end of May her condition became gradually worse, temperature varying from 100·8° to 104·2°, pulse about 130, and respirations 20. Discharge increasing; wound dressed antiseptically twice daily. There was slight puffiness of the eyelids in the morning, but no evidence of albumen in the urine. Lungs and liver normal; appetite very bad; considerable pain over the joint.

On June 11th, the patient being under chloroform, MR. Taylor removed the head of the femur by the usual operation. The bone was found to be unusually soft and pulpy in the upper three inches of the femur. Acetabulum healthy. A considerable amount of blood was lost. A large drainage-tube was inserted, and one suture to keep the edges of the wound in closer approximation. Wound dressed antiseptically. She was under chloroform an hour and a half, and was in a most exhausted state. A drachm of ether was given hypodermically whilst she was on the table. One hour after the operation she was in great pain, for which half a grain of morphia was administered. She vomited most persistently for forty-eight hours afterwards, and took only small quantities of ice and brandy. An extension apparatus of four pounds was applied. Evening temperature 100·6°.

June 12th.—Temperature 97°. Still very sick. Wound dressed, and tube removed.

15th.—Slight improvement; able to take light solids, two ounces of brandy, and four ounces of wine. Wound dressed daily with solution of corrosive sublimate (1 in 2000). Temperature 98·4°; pulse 104; respiration 22.

The femur having been found so extensively diseased, it was considered that the patient's only chance of ultimate recovery lay in removing the limb at the hip-joint. Accordingly, on June 18th, chloroform having been administered, the limb was made bloodless by Esmarch's bandage, a reserve supply of blood being kept in the healthy limb, which was liberated at the end of the operation. The aorta was controlled by Mr. Hamilton by Lister's compressor. The anterior flap was partially dissected and partially transfixed, and the posterior transfixed. Very little blood was lost, but the patient showing symptoms of collapse, thirty minims of ether were given hypodermically. No drainage-tube was inserted, and the flaps were accurately brought together for the inner two-thirds, whilst a large opening was left at the outer angle for drainage, as a considerable amount of tissue infiltrated with inflammatory products, and riddled with sinuses, was left in the posterior flap. After operation the patient had a light sleep, and then was in great pain for an hour, which was relieved by the injection of half a grain of morphia. Dosed till 3 P.M., and then had an enema of brandy (one ounce) and two drachms of Liebig's extract. No vomiting till 5 P.M. At 5.30 respiration only 11; pulse 132. —6 P.M.: Enema repeated.—9 P.M. Temperature 101·2°; pulse 132; respiration 16.

June 19th.—Passed a good night; vomited once; passed urine in the night naturally. Took ice, barley-water, and cream. Complains of being very hungry. Temperature 98·4°; pulse 136; respiration 20. Wound dressed. Slept soundly all day. No pain. Took brandy, cream, and Liebig's extract. Vomited slightly once.—9 P.M.: Temperature 100°; pulse 128; respiration 24.

From this time the patient made a rapid recovery. The stump was dressed daily with lint soaked in solution of corrosive sublimate (1 in 2000). She took solid food on the 21st. On July 10th the wound had healed, except a small sinus at its outer angle. The patient was able to sit up in bed, and partake of middle diet.

On an examination of the femur, the whole of it was found to be in a most disorganised state, the medulla breaking down under the slightest pressure. The knee-joint was diseased, the cartilages being eroded and thinned, and the synovial membrane everywhere thickened. There was also a small collection of pus about half an inch above the epiphysial line.

Reviews and Notices of Books.

The History of Cholera in India from 1862 to 1881. Being a Descriptive and Statistical Account of the Disease, as derived from the published Official Reports of the several Provincial Governments during that period, and mainly in illustration of the relationship between Cholera Activity and Climatic Conditions; together with Original Observations on the Causes and Nature of Cholera. By Deputy Surgeon-General H. W. BELLEW, C.S.I., Sanitary Commissioner, Punjab. With Maps, Diagrams, &c. London: Trübner and Co., Ludgate-hill. 1885.

WE owe the author of this treatise an apology for not having noticed it earlier. The work is a very elaborate one, consisting of 839 pages, and must have cost its author an enormous amount of labour. It may be a source of satisfaction to him to know that if we cannot aver we have read it through, we have nevertheless perused the greater part of it, and had marked so many passages for consideration, if not quotation, that we found the task of writing an adequate analysis of his views and the data on which these are based an impossible one—at any rate within the limits at our disposal. The book is a natural history of cholera, more particularly as an epidemic disease, and the strength of the author's argument rests upon a vast accumulation of details converging from certain definite directions. In an introductory chapter the author passes in review the various theories that have been put forward, and subjects them, one after another, to a fire of destructive criticism. He says that Bryden's theory—and, by the way, we might possibly cavil at the use of the term theory in this connexion,—shorn of its germ element and the hypotheses built thereon of reproduction, invasion, dormancy, revitalisation, &c., contains more of the truth of cholera than all the others preceding it put together. The records of cholera, as related in this volume, he declares, abound in evidence tending to prove that in India cholera is a phenomenon of season, controlled as regards period of appearance by geographical position, and as regards local activity by conditions of climate and soil coupled with those of the health state of the individual; that in its nature and properties cholera is strictly analogous to influenza, and also to malarious fever, and that, like those diseases, cholera is the result of atmospheric changes acting upon the system, in a manner specially determined in each disease, under certain conditions of bodily health; and that cholera, like influenza and malarious fever, without being contagious, is nevertheless infectious as a subordinate contingency concurrent with the general epidemic diffusion of the disease. In brief, it would amount to this: that cholera is powerless to spread as an epidemic, in spite of its introduction, in any area where it is not due to spread. The author deals on a uniform plan with the geography, climate, meteorology, and rainfall in connexion with the statistics of cholera mortality of the several provinces, and, as regards the vital condition of the population, he completes the description by a consideration of the food-supply in respect of cheapness or the reverse. In addition to showing the relation and interdependence of the statistics of cholera mortality, rainfall, and food-supply in India, the author dwells upon the fact that there is a remarkable correspondence in the cyclical periodicity of the disease—a periodicity which is observed not only in the returns from all India, but also in those relating to the several provinces separately, and to a considerable extent even in different geographical regions within their respective areas. This periodicity manifests itself in triennial cycles, cholera having its maximum, medium, and minimum degree of prevalence in the successive years respectively of each three-years period. Those portions of the book which deal with physical geography, topography, the monsoon and other meteorological and climatic conditions, are very perspicuously worked out. The discovery of the comma bacillus, and Koch's views in connexion therewith, are not mentioned, but it may be inferred that they would not be accepted by our author. Towards the end of the volume the pathology of cholera is discussed, and a simple, but to our minds a crude and inadequate, explanation of the course and morbid phenomena of the disease is set forth.

The outcome of our perusal of this work amounts to this: that there is a great deal of valuable information advanced about the conditions present in those places and at those times where and when cholera manifests itself, but we are really no nearer the root of the matter as regards the discovery of its true cause. There are a great many difficult points remaining unsolved. The late Dr. James Bryden, who was a man of original and philosophical mind and a *savant*, gave some of the best years of his life to the study of cholera from the standpoint of an epidemiologist and statistician, and there can be no doubt that on account of the occasional remarkable fulfilment of his forecasts his influence with the Government of India was a growing one; but labours such as his, making, as they did, great demands on the patience and intelligence of his readers, and not falling in with the practically inductive spirit of modern experimental science, have failed to attract the attention they demand. He appears to have been impressed with the idea that the cause of cholera was a something material—a vitalised something—that had a definite life history of its own, and an existence quite separate and apart from the subjects of its action. Be this as it may, his statistical labours have been continued on the same lines, and somewhat developed in the reports of his successor in office. What Bryden did mainly deductively now requires to be supplemented and complemented by inductive methods. Whether to this end we must look to micro-pathology only remains to be seen, but any assigned cause to be accepted must be adequate to cover all the phenomena. It must be remembered that cholera occurs elsewhere than in India—and the history of how it comports itself there has yet to be written,—that it apparently advances in a definite direction in its own time and in obedience to a law of its own, and that the duration of an epidemic is self-limited. During the past few years we have had it in North Africa, and it has been prevailing in Continental Europe; ships, men, and merchandise have passed freely and continuously from the infected or affected (as these happen to be regarded) places to this country without any extension of the disease hitherto. Bengal, the North-west, and the Punjab, of which our author writes so fully, have been singularly free from epidemic cholera of late years. There are some very acute sceptical thinkers who, agreeing with the author of this book, would contend that we are pursuing a phantom in endeavouring to discover the cause of cholera in the shape of a material object, organic or otherwise; that the disease itself as an epidemic will have disappeared from the application of sanitary laws in their most extended sense, and been replaced by other diseases, before this or the immediately succeeding generations have succeeded in detecting its cause; and that cholera, as we experience it, will be chronicled by some future Hecker in the epidemics of the past.

To conclude. The preparation of this history of cholera in India must have entailed upon its author unremitting toil; it is full of information, well written, and will form an excellent and useful book of reference for all engaged in medical, sanitary, or administrative work in India.

OUR LIBRARY TABLE.

The Rotifera, or Wheel Animalcules. By C. T. HUDSON and P. H. GOSSE. Parts IV. and V. Longmans, Green, and Co. 1886.—In the fourth part of the "Rotifera," the considera-

Digitized by Google

tion of the Loricate division of the Ploima is continued, including the Triarthradæ, the Hydatinadæ, and the Notammatadæ, the latter constituting the typical representations of the whole class, as well as the most highly organised, fifty-four species being figured, with no less than 130 drawings of parts and organs. The descriptions are given by two masters of the subject, and leave nothing to be desired. The fifth part is occupied with a continuation of the study of the Notammatadæ, including the Genera of Diglena and Distemma, and commences the consideration of the Loricate Ploima, including the Rattulidæ, Dinocharidæ, Salpinadæ, and Euchlanidæ. The descriptions are very animated as well as correct. Thus, speaking of Distemma raptor, Mr. Gosse observes that it presents the highest expression of animal life. He has observed amongst Rotifera—"As a fowl picks up minute atoms of food from the earth and pebbles and rubbish with which it is mingled, showing sight, observation, discrimination, selection, will,—so does this Distemma manifestly snap up its food atoms, often invisible to our eyes, selecting them with rapid precision from other surrounding atoms. The jaws are thrust out and withdrawn with a quickness which we cannot follow, and with stroke succeeding stroke quite as rapidly as a hen's beak picks up morsels, and evidently takes something at each. The way in which it pounces upon animalcules that we *can* discern, and the energetic vigour with which it seizes them, are admirable, and quite unparalleled among Rotifera, so far as my experience goes. If we could descend to his level and form a personal acquaintance with him, I am sure we should find this Distemma a person of great decision of character."

The Royal London Ophthalmic Hospital Reports. Edited by MARCUS GUNN. Part 2, vol. 11. July, 1886. London: J. and A. Churchill.—The contents of this number are—1. W. Lang and James Barrett: The Refractive Character of the Eyes of Mammalia. These observers found that, in rabbits, out of 51 eyes 14 were hypermetropic, 31 were hypermetropic and astigmatic, 1 was myopic, 3 were myopic and astigmatic, whilst 2 were characterised by mixed astigmatism. Of 20 eyes in guinea-pigs, 1 was hypermetropic, 18 were hypermetropic and astigmatic, and 1 was myopic and astigmatic. In 10 eyes of mice, 5 were hypermetropic, 3 were hypermetropic and astigmatic, and 1 was slightly myopic. Of 6 horses' eyes, 1 was emmetropic, 3 were hypermetropic and astigmatic, and 2 presented slight mixed astigmatism. Of 14 eyes in cats, 6 were hypermetropic, 4 were hypermetropic and astigmatic, 2 were slightly myopic, and 2 were myopic and astigmatic. The eyes of dogs were practically emmetropic. The refraction of the eyes of several wild animals is also given. 2. W. Lang and James Barrett: The Action of Myotics on the Accommodation. 3, 4, 5. J. Hutchinson, jun.: On a Case of Unsymmetrical Tobacco Amaurosis; on a Case of Relapsing Optic Neuritis, with development of new vessels in front of the papilla, with a plate; and on a Case of Peripheral Choroido-retinitis associated with peculiar Pigmentation of Mucous Membranes. 6. J. B. Lawford: On Eyes containing Foreign Bodies at the time of Excision, and on Cases of Cystic Degeneration of the Retina.

Coca, Cocaine and its Salts. By W. MARTINDALE. London: H. K. Lewis. 1886.—The text of this little book is printed in blue ink on green paper, as a compliment to cocaine for its beneficial effects in the treatment of disorders of the eye; the violent contrast of white and black being considered injurious to the eyesight. This blue and green arrangement is very pretty, but reading the book by gaslight is apt to produce a feeling as of sand in the eye. We may say in few words that Mr. Martindale's excellent account of coca, cocaine and its salts will give those who consult it all that they can wish to know of the history, medical and economic uses, and medicinal preparations of these valuable medicaments. Generally speaking, the preparations of coca are of most use when it is desired to act on the system at large; the salts of cocaine when intense local efforts are required; and in suppositories or ointments the pure alkaloid is the form to prescribe.

The Quarterly Journal of Microscopical Science. Edited by Professors RAY LANKESTER, THISTLETON DYER, KLEIN, MOSELEY, and SEDGWICK. August, 1886. Vol. XXVII. Part 1. London: J. and A. Churchill.—The rapid succession of memoirs on microscopical subjects which appear in this valuable journal supplies good evidence that numerous workers are devoted to the study of this instrument in this country, and are contributing their fair share to the advancement of knowledge. The present part contains: 1. The Anatomy of the Madreporaria, by Herbert Fowler Berkeley, Fellow of Owens College, Manchester, with plate 1. 2. The Formation of the Germinal Layers in Chelonia, by K. Mitsukuri, Professor of Zoology, and C. Islükawa, Assistant in Zoology, University of Tokyo, Japan, with plates ii., iii., iv., and v. 3. On the Structure and Development of the Reproductive Elements in Myxine Glutinosa, by J. T. Cunningham, with plates vi. and vii. 4. Studies on Earthworms, by W. B. Benham, with plates viii. and ix. 5. On Dinophilus Gigas, by W. Weldon, with plate x.

Fuhrer durch das Medicinische Berlin (Guide through Medical Berlin). FISCHER'S "Medicinische Buchhandlung." Berlin, 1886.—This little guide will certainly be a most useful companion for any medical visitor to the German capital. It gives plans of the chief hospitals and lists of professors and teachers, with the subjects, places, and hours of their lectures. It will also serve to a considerable extent as a general guide-book, as it contains a good map of the city, with information about trains, trams, objects of general interest, theatres, &c.

Materia Medica Labels.—Mr. H. K. LEWIS, of Gower-street, has just issued a useful collection of Materia Medica Labels adapted for public or private collections, and compiled from the British Pharmacopœia of 1885. They are printed on white paper in big bold type, and will be found very useful, not only for students, but for lecturers and teachers. The number of copies issued is small, so that early application should be made by those requiring a complete set.

The Australasian Medical Directory and Handbook. London: Baillière, Tindall, and Cox. 1886.—The second issue of this Directory, which is edited and compiled by Mr. L. Bruck of Sydney, fully maintains the high character which pertained to the first issue of the work. It contains an abstract of the principal laws affecting the medical profession in Australia; a list of coroners and medical and scientific societies; regulations of colonial universities; a general alphabetical list of the names of all known legally qualified practitioners in Australia, Tasmania, New Zealand, Fiji, Samoa, Tonga, and New Guinea, with their addresses, qualifications, &c.; and a diversity of other information calculated to be useful to those interested in the practice of medicine in the colonies. A novel feature is an appendix which contains a list of unregistered practitioners, giving the names of all persons known to practise in the Australasian colonies without being registered with any of the colonial boards, with their addresses, alleged qualifications, and other particulars.

The Tape Indicator Map of London and Visitor's Guide (C. Smith and Son, Charing-cross) is worthy of extensive public patronage. Any street or public building may be readily found by means of a tape appended to the map, accompanying which is an alphabetical list of some 7000 streets, as well as a visitor's guide.

THE LANCET.

LONDON: SATURDAY, OCTOBER 2, 1886.

UNLESS the direct representation of the profession on the Medical Council is to be a mere farce, all those who have exerted themselves to obtain this boon, and who value it at all, must resolutely resist a very ill-advised attempt that is being made to force on the general body of practitioners the three nominees of a small clique. An election by the votes of the many thousands of medical practitioners must always be a matter of difficulty, and it is absolutely essential that certain guiding principles be steadfastly maintained. First of all, there must be freedom of action. Every voter must be allowed to exercise his right without any external pressure. This was cordially recognised by the large majority of those members of the British Medical Association who were present at the meeting at Brighton, and it was accordingly decided that the Association, as such, should take no part in the election, and should not nominate, or use its powerful agencies in securing the election of, particular candidates. Secondly, care should be taken to elect only those who can really represent the wants and views of the great body of general practitioners, and in our opinion none can represent general practitioners so well as eminent members of their own body. Several candidates have come forward, and have issued their addresses and published lists of their committee or supporters. For one and all of them we would ask an impartial hearing, and up to last week we were hopeful that the election might be conducted on the lines we have drawn.

However, the entire situation has been changed by the action of the Birmingham Committee. It will be remembered that at the close of the meeting at Birmingham it was determined to issue ballot papers to the whole of the committee for the purpose of eliciting an opinion as to the three candidates most acceptable to the majority. We are informed that the vote of this committee, which now numbers about 360 members, was in favour of Mr. WHEELHOUSE (Leeds), Sir B. W. FOSTER (Birmingham), and Mr. ERNEST HART. Mr. HART, as will be seen from a letter we publish to-day, declines to be put in nomination, and it is proposed that Dr. GLOVER, whose name was fourth on the list, should take his place. So far as this poll represents the opinions of these 360 gentlemen, it is worthy of respectful attention. But two utterly unwarrantable uses are being made of it, and it is to these we would call the earnest attention of all our readers. In the first place, the assumption is made that this committee *represents* the great body of the profession. This is incorrect. *The committee represents its members, and no one else.* It has not been appointed by the profession, or even by any great body in it, and its opinions are in no way whatever to be taken as the expression of the wishes of the profession at large, still less as binding upon it. We of course recognise the perfect right of this committee or of any body of gentlemen to nominate three candidates and to endeavour to secure their election, but no such committee has any right to usurp to itself the functions of the whole body of registered practitioners; and unless the correspondence which we publish to-day is singularly misleading, the members of the electorate are alive to this, and will jealously guard their rights.

But, further than this, a bold attempt has been made to show that the Birmingham Committee is acting on behalf of and in connexion with the British Medical Association. This is a simple and absolute misrepresentation, and it must be corrected. The Association solemnly refused to take any part in the election; and even were this committee the Council of the Association itself, it could not, in the teeth of the vote taken at Brighton, presume to speak in the name of the Association in advocating the claims of three candidates. We have received many letters indignantly repudiating such conduct, and we are confident that the profession will not allow a boon which Parliament has conferred upon it as a whole to be monopolised by a caucus or a clique. The Council of the Association exists to promote the interests and aims of the whole of the members of that body, and the members must see to it that their wishes and opinions are respected, and not set aside or disregarded.

It is certainly a noteworthy comment upon the claim of the Birmingham Committee to represent the profession that no one of the three gentlemen originally selected is a general practitioner. We believe that the result of the forthcoming election will be to show that only those who have borne the burden and heat of the day in general practice, and who know its difficulties and its needs, will be trusted by general practitioners at large to speak in their name at the Medical Council.

SOME gleam of hope reaches us when we find that the urgent danger to the water-supply of the metropolis from house-boats, to which we have more than once drawn attention, has actually been the subject of "questions" in the House of Commons and the Court of Common Council, and has even been dealt with in a feeble kind of manner by a bye-law. We last week alluded to the remarks made in Parliament. Since then Mr. Deputy ASHBY has gone so far as to "complain" of the pollution of the upper Thames by house-boats; while the Lord Mayor, who is also chairman of the Thames Conservancy, replied that under the powers conferred in the Act of 1885, a bye-law had been submitted to the QUEEN in Council which prohibited such pollution. So far good. Power was necessary, and we can only regret that a year was spent in obtaining it, but we trust that Mr. ASHBY, to whom the public already owes a debt of gratitude, will increase it by continuing his questions. Let him find out whether barges are subject to the new bye-law, or to any bye-law. The barge population is much more dangerous than that of the house-boats, and being more evanescent is much more difficult to control. Above all, let him persevere till he knows how the new bye-law is to be enforced. We beg Mr. ASHBY to remember that one case of cholera, or even of choleraic diarrhœa, occurring near the intake of the great London Water Companies might infect the supply of a great part of London, and might lead to thousands of deaths. According to the carefully prepared report of the late Mr. NETTEN RADCLIFFE, the Government inspector, that was exactly what happened in the East-end of

Digitized by Google

London in 1866. The fearful epidemic in the district supplied by the East London Water Company was, in the opinion of the reporter—an opinion supported by some of the highest scientific men of the day,—directly due to the pollution of the supply by the excreta of two patients who died in Priory-street, Bow, a few days before. Who can say that this may not happen again? The Thames is a highway for commerce as well as a pleasure-ground for idlers. Who is to inspect it; who is to discover whether perfect health and perfect sanitary conditions prevail on every barge, steam launch, and house-boat that passes by, or is moored near those important intakes? Mr. ASHBY has shown that he possesses the intelligence as well as the public spirit necessary for the solution of this great sanitary problem. He or anyone who ventures to invade the officialism which clouds the question will at once be assailed with questions as to what can be done. The reply is simple. Many things may and ought immediately to be done which would lessen the present risk, and perhaps lead the way to future safety. For example, the mooring of all boats used as habitations in the reaches between Hampton and Weybridge, if not above, ought immediately to be prohibited; and a medical officer, armed with full powers and a steam launch, ought to secure the patrolling of the river throughout the dangerous region by night and day, and not only report for prosecution all who infringe the bye-law, but also remove at once to a safe place on shore any patient who seemed to suffer from zymotic disease. Why should we wait, as Spain has done, to learn from one more visit of that terrible tutor, the cholera? We know our lesson already, and yet we allow Spain, so far behind us in sanitary knowledge, to set us an example. In this connexion we may refer our readers to the weighty article by Mr. GEORGE HIGGIN, which appeared in our contemporary, *Nature*, on the 17th of June last. In that article, upon which we commented with entire approval, the association of water-supply with the fearful calamity which befel Spain last year is shown with irresistible force. But in Spain, in the districts which escaped or were touched lightly, the intakes of the water-supply were guarded by soldiers with loaded arms. All that we shall do — unless some earnest man, some sanitarian Cromwell, intervenes — is to prohibit people from defiling the river.

THE action of drinking-water on lead is a matter of such serious public importance, and is subject to so much apparent irregularity, that many investigations in regard to it have been undertaken. But the difficulties have not been entirely cleared up, and the further contribution to our knowledge which was made at the late meeting of the British Association is very welcome. The previous state of our knowledge may be summarised in a few words. The corrosion depends on the solubility of oxide of lead in pure water. The dissolved oxygen always present in water oxidises the lead, and the oxide dissolves as it is formed. Very soft waters, and above all distilled water, act powerfully and continuously. Some salts, when present, especially the salts of ammonia, increase the action, while others diminish it by a simple chemical action. Thus sulphates, carbonates, and, as was first shown by Dr. FRANKLAND, phosphates, protect the metal remarkably. When new lead is exposed to the action of water containing any of these salts, oxide is indeed formed, but is immediately converted into the very sparingly soluble sulphate, basic carbonate, or phosphate, and the lead is thereby protected by a crust, which undergoes but little further change. On the other hand, any unusual quantity of free carbonic acid favours solution of the metal, for carbonate of lead, like the carbonates of calcium, magnesium, zinc, and iron, is soluble in free carbonic acid. This source of lead pollution has, we think, been very commonly overlooked. The net result of all these observations was the belief that hard waters had but little action, while soft waters were liable to exhibit a strong action on ordinary lead pipes and cisterns. Some apparent discrepancies were gradually explained. Thus the very soft water of the Bala lake was found to have little action on lead; but Dr. FRANKLAND discovered that this was due to phosphates, which happened to be present in unusually large quantity. Other irregularities were, however, from time to time noted, and our knowledge remained imperfect, while there was no remedy suggested except the avoidance of lead, which would be very inconvenient, for block tin pipes are too expensive, while tin-lined lead pipes, although excellent, require the greatest care in plumbing, as the least exposure of lead in the presence of tin produces a voltaic action which causes rapid corrosion.

This, then, was the state of our knowledge when Professors CROOKES, ODLING, and TIDY undertook the investigation, the results of which they read at the Birmingham meeting. They commenced systematically by dividing the waters into groups, according to their action on lead, and their tables show at a glance that the mere variations of hardness do not account for the variations of lead corrosion — that, indeed, a very soft water sometimes exerted less action than one which was considerably harder. But they were soon struck by a fact previously unobserved, which afforded the clue which guided them in their subsequent work. The least action was always observed in the water which contained the greatest quantity of silicic acid. Many more observations were of course made, which confirmed the earlier ones, and then a series of synthetical experiments were undertaken, in which silica in definite quantities was added to the water before exposing it to the action of lead. At first alkaline sodium silicate was tried, but as it was found worse than useless, dialysed silicic acid was substituted with perfect success. Then followed a series of trials with powdered glass, granite, flint, agate, and chalcedony. All of these had some beneficial effect, but flint was about the best, and subsequent experiments appear to leave no doubt that, provided excess of alkali be absent, half a grain per gallon of silica in solution deprives even distilled water of any continuous action on lead. It is, however, essential that the silication of the water shall be maintained, as otherwise corrosion will set in. Here there was not only an explanation of some, at any rate, of the irregularities which had previously been most puzzling, but the suggestion of a possible remedy.

On these new lines new experiments were made, and the result was that a system was devised which appears to be at once efficient and inexpensive, and which we trust will stand further trials, and take permanent place as one of the great achievements of applied

Digitized by Google

chemistry. Filters were constructed in which the water passed downwards, first through sand, then through broken flints, and lastly through Buxton limestone. The water used was that of Huddersfield, which is very soft and dissolves much lead. After passing through the filter with uniform velocity, it was again analysed, and its action on lead again determined. The total solids in solution were found to have undergone very little actual increase—not more than about half a grain per gallon,—but enough silica had been dissolved to reduce the "lead-dissolving power" of the water to one-thirtieth, the lead-dissolving power being the quantity of lead dissolved under similar conditions in a given time. If so simple a filter will protect all water from lead pollution, water companies will have no excuse if they do not adopt it; it cannot injure, and will probably in every case improve the water in all respects.

The authors of this interesting research discuss in a separate section the question of the quantity of lead that may be permitted in drinking-water. They quote many authorities, and from them and their own observations conclude that a water is safe if a few ounces treated without evaporation with sulphuretted hydrogen give no reaction.

AT their meeting on Saturday the Metropolitan Asylums Board resolved to reinstate Dr. COLLIE, the medical superintendent of the Eastern Hospitals, and thus a tardy act of justice has been done. Dr. COLLIE, it will be recollected, was suspended from his office during an inquiry into certain scandalous proceedings at these institutions, and although it was clearly shown that personally he had had no connexion whatever with these misdeeds, he was, on account of some comparatively trifling omissions of clerical duty, almost removed from his appointment, and only permitted to return to his office on probation, after being mulcted in the amount of salary which related to the period of his suspension.

Every effort was made to offer Dr. COLLIE as a sacrifice to popular clamour. A scapegoat was urgently needed to divert attention from those who were really guilty, and there is no doubt that an act of serious injustice would have been done had not a strong feeling of indignation been roused, first among the members of Dr. COLLIE'S own profession, and afterwards among the public generally. We warmly espoused Dr. COLLIE'S cause, for we were from the first convinced of his integrity, and we felt it our duty to place every fact concerning his case in the most prominent manner before our readers, and to utilise every means in our power to ensure their being properly understood; while at the same time the metropolitan branch of the British Medical Association and the Medical Defence Association, headed by Dr. DICKSON and Dr. RICHARDSON respectively, bore witness to the esteem in which he was held by his professional brethren. We may, then, heartily congratulate Dr. COLLIE and the profession upon the successful results of these labours. We are convinced that, had less effort been made, even the narrow majority by which he was at first reinstated would have been replaced by a large majority against him.

Perhaps one of the most unpleasant incidents to which Dr. COLLIE has had to submit was his reappointment on probation to a responsible office in which he had to control a large number of subordinates. That he has succeeded in maintaining order and discipline under these disadvantageous circumstances is a striking proof of his administrative ability—ability which those who are best able to judge of the management of public institutions never failed to recognise. To Mr. GALSWORTHY, the chairman of the Board, and to Sir EDMUND CURRIE, thanks are due for their unswerving determination that the public should not lose the services of a capable officer. Had Dr. COLLIE been sacrificed, it would have been no easy task to induce medical men of any promise or ability to seek metropolitan appointments, and thus harm would have been done that might not improperly be described as a calamity. But the struggle is now ended, and we trust we have heard the last of the Eastern Hospitals scandal. We would, however, remind the Metropolitan Asylums Board that, if their institutions are to be properly conducted in future, it is necessary that the medical superintendent should be allowed to occupy the position which is defined by the Orders of the Local Government Board, and that he should be loyally supported in the performance of his responsible duties.

Annotations.

"Ne quid nimis."

DIRECT REPRESENTATION IN SCOTLAND AND IRELAND.

DIRECT representation, now that it is obtained in point of law, is by no means assured in point of fact. In England, indeed, though the profession is thrown into turmoil by grave questions as to the best modes of preserving the freedom of election while trying to secure the best candidates, not one candidate is in the field who is officially connected with the medical authorities, and the majority of the candidates are certainly *bonâ-fide* general practitioners. In Scotland the contest apparently will be between Dr. Sinclair of Dundee and Dr. Bruce of Dingwall, two good specimens of Scotch practitioners, between whom it would be impertinent in any man south of the Tweed to decide, and no man north of the Tweed can go far wrong. In Ireland, Dr. Kidd and Dr. Jacob are men who would adorn the Council; but they are officials of a corporation whose representative plays already a larger part in the Council than probably any other of its members. To associate Dr. Kidd or Dr. Jacob with Professor Macnamara would be a work of supererogation; but the only alternative for it is in the practitioners of the provinces of Ireland using the privilege conferred on them and sending a genuine general practitioner to the Council.

THE RISKS OF A SUMMER HOLIDAY.

PROFESSOR NETTLESHIP, of Oxford, has exposed in a letter to *The Times* the risks to which visitors to country districts are liable when sanitary authorities are negligent and lodging-house keepers are regardless of any interests but their own. He states that he engaged lodgings in a farm-house at Newquay, Cornwall, which were recommended to him by two respectable lodging-house keepers of long standing, who knew the state of affairs, and after being there ten days his child was taken ill with scarlet fever. He then discovered that his landlord's daughter, who was assisting in the ordinary housework, had three weeks before suffered from the same disease, and was therefore still infectious. Moreover, the children in adjoining cottages,

Digitized by Google

in one of which his laundress lived, had quite recently suffered from scarlet fever, and he was drinking infected milk from his landlord's own cows. Cases of scarlet fever, he says, were wilfully concealed from the doctor, who was also medical officer of health, so as to prevent injury to the lodging-house keepers' interests, and no steps, or next to none, were taken to disinfect the houses in which they occurred. A more scandalous state of affairs can hardly be described, and *The Times* has done a public service in discussing these occurrences in indignant terms in a leading article. Our contemporary states that Professor Nettleship has no legal remedy; but it omits to mention that the sanitary authority have ample powers, under the Public Health Act, of procuring the infliction on the lodging-house keepers of a fine not exceeding £20. If they neglect to take this step, the warning should indeed be taken to heart by intending visitors, and holiday-makers should avoid Newquay as they would any other pestilential locality. But this is a case in which the Local Government Board can give assistance, and we trust that the publicity given to Professor Nettleship's story may have the effect of pressure being put upon the local authority to enforce the provisions of the Act of Parliament. Whether they will do so or not is doubtful, for it is an instructive commentary upon the history which has been given that public health services are valued at Newquay to this extent, that the remuneration of their medical officer of health is an annual payment of £10.

THE RABIES AND ANTHRAX ORDERS OF THE PRIVY COUNCIL.

THE Privy Council have just published two orders under the Contagious Diseases (Animals) Act, dealing respectively with rabies and anthrax. These orders prescribe the duties of local authorities and their officers, and empower the former to make regulations for controlling and prohibiting the movements of animals infected, or suspected of being infected, and for cleansing and disinfecting places occupied by these animals. The regulations which can now be made for muzzling and controlling dogs are very comprehensive, and much care will have to be exercised by local authorities so as not to attempt to do more than can reasonably be carried out. The order has wisely not required the hides of animals dying from rabies to be slashed, and thus the risk of infection of the ground through the saturation with blood is avoided. The orders and the regulations which will be made thereunder will doubtless prove of some value, but their chief use will be in enabling some idea to be formed of the number of cases of these diseases which occur throughout the country.

RUPTURE OF THE BLADDER.

THE result of suturing the rent in cases of ruptured bladder has not hitherto been successful, but the opinion held by surgeons, that it is the right treatment to pursue in such cases, receives strong confirmation from a case now under the care of Sir William Mac Cormac in St. Thomas's Hospital. The patient, a strong, florid, healthy man, aged thirty-three, injured his abdomen by running up against a post, about fifteen hours before he applied for admission. Interrupted silk sutures were used for the bladder, the rent in which was about three inches long, a catheter was tied in, and the abdomen drained by a glass tube. There was a large amount of urine in the peritoneal cavity, which was washed out with a solution of boracic acid. The operation was performed on the 22nd ult. The patient passed urine the following day, when the catheter was removed. The drainage-tube was taken out on the 24th, and there has been no fever or other symptom since the operation.

HOW LONG TO SLEEP.

IT is manifestly impossible to lay down any universally applicable rule as to the number of hours which it is desirable to sleep. Probably no two persons require precisely the same amount of slumber, and it is scarcely likely that any person needs the same length of sleep on all occasions. Even the most monotonous lives involve the expenditure of varying quantities of energy, and make differing demands on the stores of nerve- and muscle-power on several days. We do not, of course, mean to imply that sleep is *the* season of recuperation. That is unlikely in view of the ascertained facts in relation to tissue-feeding and physiological change; but it is nevertheless true in practice that prolonged or exceptionally severe exertion, whether of brain or muscle, requires a correspondingly lengthy or deep repose. Speaking broadly, sleep is the state in which the fires are, so to say, damped down and the machinery has opportunity for cooling. The bow is, as it were, unstrung, and may recover its elasticity during the recurring periods of slumber. The great point is to secure what Bichât characterised as general sleep made up of particular sleeps. The whole body should be rested—so far as any avoidable demand on its energy is concerned—during sleep. The Irishman, who explained that a short sleep did for him because when he slept he "paid attintion to 't," uttered a truth in his witticism. If sleep be thorough, then a short spell will do more good than a much longer duration of sleep that is incomplete and imperfect, both in its nature and in its effects. We cannot discuss the physiology of sleep in this place, but two or three propositions, based on experience and observation, may be briefly set down by way of suggestion worth thinking out for special application in individual cases. Sleep is a distinctly natural function, and therefore, both as regards its induction and management, ought to be performed in conformity with natural laws. That it is a state which should recur periodically is evident from the rotation of day and night, and approximately we ought to go to sleep when the natural light fails and wake with the sunrise. It will therefore be evident that Nature meant us to sleep longer in the winter than in the summer, for the sufficiently plain reason that the maintenance of animal heat during the cold season necessarily requires a larger consumption of energy than is expended on this vital purpose in the warm season. It has been alleged that the organism takes in and stores just as much oxygen during sleep as it has expended during the waking hours, and when the reserves are replenished wakes; but this is only a half-truth, in so far as it is a truth at all. What happens is rather a rest from the rapid movements of waking life, during which the slower activities of function have time to overtake the faster ones. Recuperation by nutrition is a more tardy process than consumption by work and heat production, and if the hare were not to sleep the tortoise would be left hopelessly behind. It is essential to health that the tortoise should not lag far in the rear, and sleep must be just as long as will enable the laggard nutritive processes to overtake the impetuous destructive processes. Practically, therefore, a man should sleep until he is refreshed. The mistake many persons make is in attempting to govern what must be a matter of instinct by volitional control. When we are weary we ought to sleep, and when we wake we should get up. There are no more vicious habits than adopting measures to "keep awake" or employing artifices, or, still worse, resorting to drugs and other devices to induce or prolong sleep. Dozing is the very demoralisation of the sleep function, and from this pernicious habit arises much of the so-called sleeplessness—more accurately wakefulness—from which multitudes suffer. That day is not the time for sleep is evident upon the face of the fact that Nature has provided

Digitized by Google

the night, wherein no man can or ought to work. Instead of trying to lay down arbitrary rules as to the length of sleep, it would be wiser in a common-sense and physiological way to say, Work while it is day; sleep when you are weary, which will be at night if the day has been spent in honest and energetic labour. When you wake, rise; and if the day's work has been sufficiently well done, the time of waking will not be earlier than sunrise. The difficulties about sleep and sleeplessness—apart from dreams—are almost uniformly fruits of a perverse refusal to comply with the laws of nature. Take, for example, the case of a man who cannot sleep at night, or rather who, having fallen asleep, wakes. If he is what is called strong-minded, he thinks, or perhaps reads, and falls asleep again. This being repeated lays the foundation of a habit of waking in the night and thinking or reading to induce sleep. Before long the thinking or reading fails to induce sleep, and habitual sleeplessness occurs, for which remedies are sought and mischief is done. If the wakeful man would only rouse himself on waking, and get up and do a full day's work, of any sort, and not doze during the day, when next the night came round his sixteen or twenty hours of wakefulness would be rewarded by a sleep of nine or ten hours in length; and one or two of these manful struggles against a perverted tendency to abnormal habit would rectify the error and avert the calamity. The cure for sleeplessness must be natural, because sleep is a state of natural rhythmical function. You cannot tamper with the striking movement of a clock without injuring it, and you cannot tamper with orderly recurrence of sleep without impairing the very constitution of things on which the orderly performance of that function depends.

THE PROGRESS OF CHOLERA.

WITH but few exceptions, cholera is rapidly diminishing in most of the towns and provinces hitherto infected in Italy, and although a few fresh places have been attacked, the mortality in them is comparatively small. The largest number of deaths is occurring at Torre dell' Anunziata, Taranto, Ferrara, and Cagliari; but even in these places the fatal attacks only vary from about two to five a day. So also, speaking generally of Austro-Hungary, there is a decline in the extent of the epidemic. Dalmatia is reported to be practically free from the disease; in Istria the number of fresh cases is only small; at Trieste there has also been a diminution in the number of attacks and of deaths; and at Raab, on the Danube, no material extension has taken place. Pesth alone remains seriously infected, the cases and deaths during the past week having averaged some 35 and 15 a day respectively; but, having regard to the sanitary condition of the town, a much more rapid extension might reasonably have been anticipated. Thus far, there is no report of the disease having attacked Buda, on the opposite side of the Danube.

"VIEWING" REMAINS.

SURELY it ought to be settled once for all whether jurors *must* needs view remains. As a matter of fact, in so far as it is permissible for us to express an opinion on a legal question—the lawyers are not too modest in their expressions of opinion on medical questions,—there is no better foundation for the practice of viewing remains than the traditions of the coroner's court. It would have been an excellent thing if the jurors who were on a recent occasion compelled by a coroner to view the body under threat of fine had refused to go, and let the coroner do his worst. We greatly question whether the fine could have been enforced or committal to prison actually carried out in default of payment. Someone should try the eventuality by arrangement with some coroner who takes a sensible view of the matter. It is cruel to compel men, who are generally the fathers of families dependent on their health and energy of mind and body, to expose themselves to the most depressing influences with no better purpose than the enactment of a perfectly useless farce. Nothing whatever is gained by the visit of the coroner's jury to the deadhouse or apartment where the body is lying. No absurd rule compels a jury of assize to view the remains of a murdered man, and why should a jury of inquest be compelled to perform that grim ceremony? The evidence of "view" is not even made part of the case, for evidence of the fact of death is always taken from a medical or some other witness. If there be a compelling law, which we take the liberty of doubting, the sooner it is repealed the better, for at the present moment needless risks are run and nameless injuries to body and mind are done by this absurd custom, and with not a vestige of good to compensate.

TONSILLITIS IN ADOLESCENTS.

DR. C. HAIG-BROWN has published his M.D. thesis upon a very common affection, of which in his capacity as medical officer at Charterhouse School he has necessarily had considerable experience. The monograph contains much matter of interest—such as, for example, the fact that 105 out of 127 consecutive cases occurred in lads between the ages of fourteen and seventeen; the undoubted association of some cases with the rheumatic diathesis, or more immediately as a precursor of an attack of acute rheumatism; the humidity of the atmosphere as favouring tonsillitis, and the equally notorious influence of defective drainage. Dr. Haig-Brown is convinced of the contagiousness of tonsillitis, and sketches two epidemics that occurred in his practice, from the study of which he concludes that the contagium is most virulent at the commencement of the disease, at a stage when it is often overlooked. Amongst complications he discusses very fully the development of cardiac murmurs, which were met with in 9·4 per cent. of cases where there was no previous history of rheumatism. In eight cases out of 345 the evidence was conclusive in favour of endocarditis, for they terminated in chronic valvular disease, and in three there was distinct evidence of pericarditis. It would have been valuable to have had statistics upon the occurrence of albuminuria, but this is a point which is not specially touched upon. As to treatment, the opinion is expressed that, like acute pneumonia and many specific fevers, tonsillitis runs its course uninfluenced by drugs, and this applies not only to guaiacum, aconite, and chlorate of potash, but also to salicine and the salicylates, with the reservation that the latter may possibly in some cases avert an attack of rheumatic fever.

HEALTH OF SEWERMEN.

IT is a very old story that the classes habitually engaged in particularly unhealthy occupations are, generally speaking, healthy. More than forty years ago, when the science of "Vital Statistics" was in its infancy, the newspapers announced with many expressions of amazement that the "nightmen"—the men who emptied the cesspools—of London were healthy and long-lived. It must be so. Only very strong, or more accurately insusceptible, persons could engage in such an avocation with impunity, and having been habitually exposed to the effluvia for some time, they would naturally become, as it were, inured to the contact with filth. It is therefore not in the least degree surprising to be told that the sewermen of Chelsea "showed marvellous health and activity." The strangeness of the story would come out if the facts lay the other way. Let no mistake, however, be made as to the moral. Arsenic is not the less an active poison, working death with certainty, because there are arsenic eaters who thrive and

Digitized by Google

grow fat on what kills men not habituated to its use. If the whole population lived in the sewers, the mortality would be considerable, because the weakly and susceptible would be killed off with great celerity, but the survivors would be extremely unlikely to suffer from either typhoid fever or diphtheria. If the Vaccination Acts were repealed to-morrow the deaths from small-pox would be very numerous, and again, as when the elderly part of the present community were young, the streets would be full of miserable creatures with wofully pock-marked faces, but those who had either survived or resisted the disease would not be likely to develop it in their own persons. We fail to see the force of the remark that any special class of inured persons are free from the maladies which they have outlived, and when such remarks are made they ought to be explained, or qualified by reference to the facts that elucidate them.

THE METROPOLITAN RAILWAY "MYSTERY."

FOR some time the public mind was exercised to account for the grievous injury inflicted on Mr. Moritz Fischer on the evening of the 22nd ult., whilst travelling on the Metropolitan Railway. From the first the theory of suicidal intent was not seriously entertained, as there was no apparent adequate motive to such an act, and, moreover, no weapon was found in the carriage or upon the line with which the injured man was likely to have attempted to take his own life. By whatever means the blow was given, it was clear that the force must have been great, for we learn that the frontal bone was fractured and the brain lacerated. A contemporary says "it was an incised wound, and must have been inflicted with a moderately sharp instrument, and on the edges was some black matter evidently from the weapon with which the wound had been inflicted." We now know beyond all reasonable doubt that the weapon was the projecting edge of the inner tunnel close to Praed-street Station. The term "incised wound," though not absolutely incorrect is somewhat misleading, for to the unprofessional mind it conveys the idea that a "moderately" or otherwise sharp instrument must necessarily have been the agent; whereas nothing is more common than to meet with cases of linear wounds of the scalp caused by a blow delivered by a very blunt body. This is explained by the fact that the lacerating force is received upon a curved surface, so that the counterpressure of the skull cuts, as it were, the soft tissue intervening between the bone and the external object in a more or less linear manner. Obviously the degree of curvature and the angle at which the blow is delivered will modify the nature and appearance of the wound. It is by no means rare, even for medical witnesses, to testify in police-courts that certain linear wounds must have been caused by "somewhat sharp instruments," and yet in many of these cases we imagine that if all the facts were brought to light the reverse would be found to obtain. This is an important point, because upon the medical testimony the fate of a prisoner may rest. Let it be remembered that a linear wound is not necessarily an incised wound in the strict sense of the term. Careful observation of a linear wound inflicted by a blunt instrument, such as a rolling-pin, will show that the tissues skirting the "solution of continuity" are bruised; that is to say there is interstitial hæmorrhage far beyond in amount the most that is ever found in a truly incised wound. In Mr. Fischer's case the problem has been solved. The unfortunate gentleman must have projected a considerable part of his body beyond the window of the carriage for his forehead to have come in contact with the arch. This may have been with the purpose of ascertaining the position of the train, or, as has been suggested, to watch the movements of passengers in the adjoining compartment. Be this as it may, the unfortunate incident should serve as a warning to the numerous passengers travelling on the Metropolitan Railway that, if they set any value on their lives, it is wise for them to keep their heads clear of such obstructions as tunnel walls. A "danger" notice ought to be posted in the carriages of the company warning against the possible fatal consequences of such an act as Mr. Fischer seems to have committed. As regards violence at the hands of another, in Mr. Fischer's case we need only say that the evidence was altogether against it. No robbery had been committed, the compartment of the carriage was in no way disarranged, and there was no sign of anyone other than Mr. Fischer having entered or left the part of the train in which he was found bleeding and unconscious. We commend the vigilant search instituted by the railway officials and the police, and congratulate the public upon the satisfactory solution of the mystery.

AMBULANCE INSTRUCTION TO KEEPERS AND GILLIES.

THE occurrence of a series of gun accidents during the active shooting season of autumn—some necessarily fatal from the extent of injuries inflicted, but others more dangerous from the loss of blood than from the extent of the wound—suggests that sportsmen should require every keeper and gilly to undergo a course of ambulance instruction, or, where this is impracticable, one of the popular publications issued by the St. John Ambulance Association might be supplied. A simple sketch of the human framework—just showing the bones and the parts where fractures most commonly occur, and an outline of the main arteries and veins, with the points at which pressure can be most effectually applied to arrest hæmorrhage—might hang up in the keeper's lodge. It is a matter which men liable to accident take a deep interest in, and it at the same time quickens a taste for the study of nature. We do not suppose any instruction such as is here indicated, or even the highest surgical skill, could have arrested the fatal hæmorrhage in the gunshot wound received by Lord Dalkeith, heir to the dukedom of Buccleuch, while out deer-stalking in a remote part of Scotland. But had the wound been less severe, and the brachial artery alone lacerated high up in the arm, there would have been no one but the keepers and gillies to render such simple surgical aid. A very little education in the principles of "First Aid to the Wounded" would enable bleeding from a wounded vessel to be staunched and life saved till skilled surgical assistance could be obtained.

COCAINE IN HAY FEVER.

DR. SETH BISHOP, in a lecture delivered at Chicago Medical College, points out that three conditions are requisite to the existence of a paroxysm of hay fever. "Firstly, abnormally sensitive nerve centres; secondly, a hyperæsthetic condition of the peripheral extremities of the nerves; and, thirdly, the presence of one of a vast number of irritants." No curative treatment has been discovered, and preventive treatment has led sufferers to seek relief in mid-ocean or on mountain-top. As palliatives, quinine, chloral, and morphia internally, and quinine, chloroform, and carbolic acid by inhalation, are the most useful—quinine, perhaps, being the best. The powerful local anæsthetic action of cocaine has led to its employment in hay fever, but the applications require to be repeated so often as to be open to the risk of exciting toxic effects from the absorption of the drug. Dr. Bishop has devised an insufflator, whereby a 6 per cent. powder of cocaine and sugar of milk can readily be applied, and with striking palliative results. He describes the local action of cocaine upon the mucous mem-

Digitized by Google

brane as primarily productive of anæsthesia and anæmia, followed unfortunately by swelling and hyperæmia to such an extent sometimes as to necessitate the abandonment of the drug. In its general toxic effects it resembles, when taken in large doses, opium-poisoning, but the pupils may sometimes (not always, as when applied locally) be dilated. Alluding to cauterisation of the mucous membrane, he warns us that this treatment may induce an attack of true asthma without curing the hay fever, as in a case personally known to him.

DESPATCHING" THE VICTIMS OF HYDROPHOBIA.

IT is startling to find that in these enlightened times there lingers among the ignorant and prejudiced the notion that the victims of disease are sometimes "despatched" to "put them out of their misery." In connexion with a recent case of hydrophobia a particularly "absurd rumour" of this nature was raised. The function of the medical profession is to save life, not to kill, even "in mercy." When the subject of a mortal disease is in agony the resources of our art, medical and surgical, are ransacked for means to ease pain and prolong existence. The public only imperfectly understand how intense and persevering is the desire and endeavour of the profession to spare suffering and save life. We occasionally hear "doctors" and "surgeons" spoken about as though they were indifferent to the misery of their patients. A long experience and wide observation lead us to assert unhesitatingly that nothing can be more unjust and groundless than this charge. It is inconceivable that any man who has that inner view of the utter wretchedness of disease and the terrible nature of death which a practitioner of medicine possesses can be indifferent to the mental or physical sufferings of his patients. The wear and worry of professional life for those whose mission it is to minister to the sick consist mainly in the anxiety to do the very utmost which art empowers us to do in the discharge of a heavy responsibility to help the poor people who look to us for succour. Medicine and surgery are agencies for the rescue of those who have fallen into the toils of disease, and who are in peril of death. We care not how these troubles may have come upon them except in so far as the recognition of these causes of sorrow and suffering may avail to save others; but for the sick themselves our only and earnest care is to cure, or, if that be impracticable, to relieve them.

CLASSIFICATION FOR MEDICAL LIBRARIES.

MR. J. B. BAILEY read an instructive paper at the annual meeting of the Library Association, held at Plymouth last month. It was concerned with the best mode of classification for scientific and medical libraries. Mr. Bailey is strongly of opinion that the best plan is to have a properly made and kept index catalogue. Shelf classification he regards as almost useless, especially with regard to the periodical literature of the day. "Any bibliography ignoring the papers printed in the numerous journals and Transactions would be absolutely useless; in fact, it would not be worth the time occupied in compiling it. The impossibility of showing on the shelves anything except separate publications seems to me to at once stamp this system as useless in the class of libraries" under discussion. "With a good index catalogue all the chief periodical literature can be laid before the student, and I venture to think that no catalogue has yet been issued in which this has been so thoroughly and so well done as in the Index Catalogue to the Surgeon-General's Library at Washington." The Royal Medical and Chirurgical Society is to be congratulated on the possession of a librarian who takes such interest in his work.

"HARASSING THE SOLDIER."

UNDER the above sensational title a letter recently appeared in *The Times* from Surgeon-Major Davy of the Army Medical Staff. The object of it seemed to be to call attention to the injurious effects arising, in his estimation from the training which the recruit is put through on joining the army. He advances the opinion that the setting-up drill interferes materially with the process of respiration, "constituting grave lung embarrassments, together with (so intimately are the lungs and heart interdependent) a palpitating heart, in men who have been for many minutes standing perfectly still." Now, it is undoubtedly a matter of importance to ascertain whether the system of drill is such as to produce serious lung or cardiac derangement. But we are bound to say that Dr. Davy has failed to adduce any satisfactory evidence that such is the case. We are quite prepared to admit that drill, if continued too long at a time, or if the recruit is kept in one position, or at one set of motions too often repeated, will be very likely to induce exhaustion, and that watchful care is therefore necessary to prevent mischief; but we believe that with such care no harm is likely to be caused by the training. In support of his hypothesis Dr. Davy quotes some observations made by Dr. Parkes many years ago with reference to the great amount of lung disease in the Guards, but he does not accept Dr. Parkes' view of the cause of it; and he omits all reference to the fact that since the period at which these observations were made, a remarkable reduction has taken place in the mortality of the Foot Guards—a reduction from 17·5 per 1000 of the strength to 7·28 on the average of the last ten years. The difference has been chiefly in deaths by lung disease, and this without any corresponding change, so far as we can learn, in the system of drill to which Dr. Davy attributes such injurious consequences. But there is another mode of testing his opinion. Perhaps there is no point on which a more marked difference exists in the army and navy than their drill. But if we compare the losses in the two services by death and invaliding from lung and heart disease, the results are most remarkable. In the army serving at home the deaths and invaliding on the average of five years, 1880-84, amounted to 5·86 by tubercular lung disease, and 5·19 by heart disease; while in the navy on the home station, for the same period, they were 5·20 and 5·77 per 1000; so that there has been a slight excess of lung disease in the army, and of heart disease in the navy. Surely if the system of drill were so important a factor in the production of these diseases, as Dr. Davy asserts, it could not have failed to manifest its influence in a marked manner. During the civil war in America a large number of men became the subjects of "irritable heart," the form which chiefly gives rise to the invaliding for heart disease in our service; but as the men were sent off at once to join the army, without any previous training, it could not be in any way a result of drill. It was believed by the medical officers to be chiefly caused by hard field service, the abuse of stimulants, and the excessive use of tobacco. To the two last-named causes, and to long-continued exposure to excessive heat, we are disposed to attribute much of its prevalence in our service. We regret that Dr. Davy has based an unqualified condemnation of the system of drill on such very unsatisfactory data. One unfortunate result of such a course must be to shake the confidence of the authorities in the recommendations made by medical officers, when they find serious charges brought and sweeping changes advised upon such inadequate grounds. The proper course would have been to have brought the subject to the notice of the Director-General, with such evidence as Dr. Davy possessed to show the injurious working of the present system. We have no doubt that Sir T. Crawford would have then had the question fully investigated by experienced and competent officers,

Digitized by Google

and, if necessary, have brought it under the consideration of the Commander-in-Chief. We must also take exception to the channel through which the subject has been brought forward. Surely the discussion of an important sanitary question, based on physiological considerations, if deemed necessary at all, would be more appropriately conducted in the professional journals, and more likely to lead to satisfactory results than an appeal through the daily press to a class of readers who may be fairly supposed to have no knowledge of the subject.

SALICYLATED BEER.

THE Parisian journals are discussing the question of the propriety of the consumption of beer that has been treated with salicylic acid in order to prevent its deterioration. The matter should in our estimation lie in a small compass. Salicylic acid is a powerful drug which has been in general use for a sufficiently long time for the medical profession to learn that it should by no means be prescribed without the exercise of due caution. It is not a substance that can be taken inwardly in the same *ad libitum* fashion as gentian, quassia, and the like. In many individuals salicylic acid produces serious symptoms, and even depression of the heart's action. These results are most frequently seen in those patients in whom the renal and hepatic functions appear not to be acting efficiently. Young children and the aged are more susceptible of its influence than those in robust health. Therefore simply looking at the matter from the medical or hygienic point of view, the employment of salicylated beer should be condemned. The same reasoning holds good for the salicylage of foods in general. The quantity of salicylic acid employed is by no means inappreciable. It has been computed that the salicylated beer of Paris contains more than twenty centigrammes of the acid in every litre, so that a considerable quantity of the noxious agent could be taken into the system by the thirsty beer consumer. There are grounds for believing that the rate of elimination of the antiseptic drug is by no means rapid, and any congestion of the kidneys or liver would certainly retard its excretion in great degree. Again, we are not sure, even supposing that the substance were excreted completely, that constantly having the tissues bathed by a weak solution of salicylic acid would be unattended with danger. Salicylic acid is a member of a dangerous group of chemical bodies, the best known of which, carbolic acid, is a most rapid and fatal poison.

GASEOUS MEDICATION PER RECTUM.

BERGERON says that this therapeutic method is based on the physiological principle established by C. Bernard that the introduction by the rectum of substances even of toxic nature is not dangerous so long as elimination by the respiratory passages is not hindered. It has been also observed that a current of carbonic acid gas may be introduced in indefinite quantity into the rectum without giving rise to any ill effects, provided certain precautions be adopted. After having tried the effect of a number of balsamic parasiticides and antiseptics, the author has concluded by giving preference to sulphurous mineral waters. A current of four or five litres of carbonic acid gas traversing from 250 to 500 grammes of sulphurous mineral water (Eaux-Bonnes, Allevard, Saint Honoré, Challes) is introduced by the rectum twice every twenty-four hours. After the employment of these measures for a few days, it has been observed that the cough has been greatly relieved, the expectoration has been profoundly altered in quality and its quantity reduced to a very low ebb, the perspirations have been stopped, the general state has been correspondingly improved, and this not only in incipient phthisis, but also in the confirmed stages of the disease.

HEALTH OF NORWICH.

NOTWITHSTANDING the recent fall in temperature, the death-rate from all causes, and especially from diarrhœa, continues to increase in Norwich. The mean annual death-rate in this city during the twelve weeks ending last Saturday was equal to 28·2 per 1000, and the rate in the last three weeks of that period was 35·1, 40·8, and 43·7 respectively. It may be noted by way of comparison that the mean rate during the same period was but 20·4 in the aggregate of the twenty-eight towns, and did not exceed 18·9 in London. The main cause of this excessive mortality in Norwich has been the exceptionally excessive fatality of infantile diarrhœa. Norwich is one of the large English towns in which the mortality from this cause somewhat constantly exceeds the average for large towns. In the summer quarters of the ten years 1875-84 the mean annual death-rate from diarrhœa in Norwich was equal to 3·6 per 1000 of the population, against an average of 3·0 in the twenty-eight towns. In the summer of 1885, however, the rate from this cause fell to 0·9 in Norwich, against an average of 2·0. The mean diarrhœa rate in the past twelve weeks now under notice was 8·4 in Norwich (considerably exceeding the rate in any of the eleven preceding summers), against a mean rate of but 3·6 in the twenty-eight large towns. With reference to this remarkable and disastrous mortality, mainly of infants, it is well to bear in mind the epidemic of typhoid fever that prevailed in the city during the early part of 1885 and the subsequent inspection of the city by Dr. Airy, a medical inspector of the Local Government Board. Dr. Airy attributed the epidemic in great measure to the foul condition of the privies, and recommended that the bins should be reduced in size, and that steps should be taken to close certain dangerous wells that were known to exist. Mr. Crosse, the medical officer of health for the city, in his report for 1885, dated in May last, writes: "Nothing has been done in either direction, and yet the complaint (typhoid fever) has comparatively speaking, disappeared." There remains, however, for the serious consideration of the sanitary authority of the city, in consultation with their medical officer of health, the probable connexion between the grave sanitary defects pointed out by Dr. Airy, and the exceptional mortality from diarrhœa that has prevailed during the past summer and early autumn.

PERCHLORIDE OF MERCURY AS AN ANTISEPTIC.

THE danger of bichloride of mercury as an antiseptic, whether as a dressing in surgery or a douche in antiseptic practice, is being unpleasantly illustrated in many cases. The *Journal of the American Medical Association* reports a case of supra-pubic cystotomy in a man of seventy years for the extraction of two stones the size of walnuts. The patient was much collapsed after the operation, but progressed favourably o the eleventh day, when severe diarrhœa with much rectal pain and tenesmus came on; later the evacuations were tinged with blood and the patient complained of a metallic taste in the mouth. These symptoms were properly attributed to the action of the bichloride irrigations, which were used twice a day. When they appeared the irrigations were discontinued, with some improvement, but death occurred on the thirty-sixth day. Professor Dennis, in a paper on Antisepticism, in which he almost out-Listers Lister, admits this risk of the bichloride. Various continental writers have shown the risks. Dr. Lucien Butte has been at pains to collect fatal cases, and has published an article on the subject in the *Nouvelles Archives d'Obstétrique et de Gynécologie*. The strength of the solutions used were from 1 in 750 to 1 in 1500 parts. He has collected thirty fatal cases. In these, mostly parturient, there was sanguinolent and fetid diarrhœa, with acute rectal

Digitized by Google

pain. The mouth is seldom affected. The chief post-mortem lesions are a gangrenous enteritis and deposit of amorphous masses of oxalate of lime in the kidney, not always present, but pathognomonic when it occurs. The *New York Medical Record*, in giving an interesting abstract of Dr. Butte's paper, maintains that with proper precautions the solutions may still be used, observing that though they may have killed tens they have saved thousands. This is not quite satisfactory, and we should advise obstetricians to be content with less virulent germicides.

NEWSPAPER THERAPEUTICS.

THE custom of giving medical advice in the newspapers has of late years become a somewhat common one. Whatever motive of expediency may be urged in its favour by those whose practice it is, more than enough for its condemnation may, we are sure, be said on the other side. There are many points in diagnosis which can only be made out by personal examination; nay, statements in this connexion are commonly of little value. Even facts of life history cannot always be correctly learned from a written description. There is, therefore, inseparably connected with this singular mode of practice the danger of misinterpretation, the unfortunate results of which may at any time react upon the patient. We may be told that if care be taken to select simple cases, no serious evil can arise. The argument even so put, however, is a weak one. It amounts to this, that where the ailment is slight, it does not matter much if a little mischief is done. By it a wrong principle is not excused by the impotence of its practice. The trifling ailment, moreover, may be aggravated by delay or mismanagement, while even a cautious beginning in such haphazard treatment will often become the cue for heedless enterprises of a like kind. It will also be seen that while the tendency of such procedure is to debase the quality of medical advice, its effect must be to augment the already inordinate value which is assigned by many to drugs and other means of cure in themselves.

SUBSOIL FILTH IN WESTMINSTER.

THE assurance given in a letter to *The Times* from Mr. Phillips, resident engineer at the Houses of Parliament, that the subsoil filth he has discovered in Westminster is "comparatively harmless," as it is hermetically sealed down by the overlying bed of gravel and water therein, nevertheless must leave an uneasiness of mind in those residents in Westminster who concern themselves with the sanitation of the locality. With his assurance of the comparative harmlessness of this filth, Mr. Phillips concludes his letter by saying: "Notwithstanding this, the unpleasant fact remains that from 26 ft. to 36 ft. below the present surface of Westminster this objectionable stratum of sewage-water exists." In the various "well-sections," published in the Geological Survey of the London Basins, no mention is made of this filth-bearing stratum in Westminster. Thirty feet or so of made ground, sand and gravel, have to be passed through before the London clay is reached, but in none of the published accounts supplied by various engineers and artesian well-sinkers to the Government inquiry is any mention made of the sewage-bearing stratum Mr. Phillips has discovered. Had not the account been given by one so reliable as the Government engineer, the offensive stratum might have been suspected to be of the nature of that commonly found even in such uninhabited localities as the Bagshot Sands, where, as elsewhere, at the junction of a porous stratum of sand or gravel, especially the former, with an impervious clay, a bed of organic matter is found. This is nothing more than the washings from the rainfall on the higher water-shed, filtered out by the porous medium through which it passes to reach the valley. Such deposits, even when of purely vegetable origin, are often very offensive, and when tapped for a water-supply the water is very offensive also. Some assurance is needed that the wells of Westminster, which have been sunk for a pure supply from the chalk, are free from this sewage. After passing the upper porous 30 ft. of sand and gravel, about 100 ft. of London clay has to be passed through, and then various strata, till the chalk is reached at from 250 ft. to 300 ft. Any insecure joint in the cylinder would admit the filth and contaminate the water, and even some might pass down by the side of the boring, which it has been known to do, notwithstanding the assurance of engineers to the contrary.

GRANULOMA FUNGOIDES.

AN account of a case of the rare affection, Granuloma fungoides, has been published by Drs. Carl Hochsinger and Eduard Schiff of Vienna. Their paper also appeared in the *Vierteljahreschrift für Dermatologie*, No. 3. 1886, but the authors were not enabled to revise it, and they have therefore felt bound to issue it in a separate form. It will be read with interest here in connexion with the remarkable case described by Dr. Payne last session at the Pathological Society. The disease began in 1877 as a chronic eczema of the back, which gradually spread over the body. In 1883 the head was attacked, and soon became the seat of the characteristic ulcerating nodules. The patient, a female, died in November, 1885. The authors give a historical sketch of the affection, and describe its histology as a nodular formation of granulation tissue replacing the normal tissue of the cutis and the papillary body. A delicate reticulum supports the round cells, and in no part are any giant-cells detected. The transition to healthy skin is gradual. The new growth is not very vascular, and as it spreads it rapidly destroys the cutaneous capillaries. Described previously under such names as *lymphadenie cutanée*, "sarcomatosis generalis," its alliance with specific inflammatory formations has been proved by the discovery of micro-organisms in the tissue; so that Rindfleisch gave it the name of Mycosis fungoides. Hochsinger and Schiff in the present case ascertained the presence of streptococci in the vessels, leading to the obliteration of the latter; and they instituted a series of culture-experiments, which are described in their paper, and which prove that the micro-organism is distinct from the pyogenic forms.

DANGEROUS DRAIN CONNEXIONS.

MR. CROSSBER DIXEY, M.R.C.P. Ed., has published a complaint as to the sanitary administration of Dover in connexion with the system of house drainage. The sanitary authority having required that the drains of a house into which Mr. Dixey had entered should be connected with the main sewer, he was informed by the landlord that all that was required had been carried out. Soon after this the house was flooded with sewage, and it was then found that the drain had been made to empty into another, the former being a foot above the latter, and that a disused brick drain remained under the house. The complaint is that if the authorities compel alterations in the system of drainage they should see that they are properly carried out. It is certain that such a condition as that described should never be allowed to exist, but at the same time we are bound to admit that the sanitary authority can only compel such modifications in house-drainage, as remained in this case after the new junction had been made, by proving that the existing drains cause nuisance or injury to health, and this it is at times by no means easy to prove. But if it be known to a sanitary authority that such a junction as that described at this house exists—and it ought to be known—then the authority

Digitized by Google

should at least advise the tenant to get such repairs effected as are necessary for the purposes of health. From Mr. Dixey's letter we gather that the alteration was made before he entered the house, and that it was done by the landlord. If so, it is possible that the landlord may have been informed of the dangers connected with the house. But under any circumstances some one ought to be appointed to see new drains and junctions before they are covered in, and to prevent such work as is complained of from existing unknown to the tenant.

THE LEAVESDEN SCHOOLS.

WE commented some weeks ago upon the treatment to which Mr. Adams Clarke, the medical officer of the Leavesden Schools, was subjected by the guardians of the parish of St. Pancras. The local newspapers have kept us informed of the proceedings of this body, but we have refrained from commenting upon them until the inquiry was held by the Local Government Board, which was evidently the only outcome of the situation. It is now with much satisfaction that we publish an extract of a report by Dr. Bridges, Local Government Board inspector. Dr. Bridges has fully endorsed Mr. Clarke's opinion, that the causes of any defects in the Leavesden Schools are to be found in conditions that the guardians can alone remedy, and which Mr. Clarke has repeatedly pointed out to them. The attempt made by the guardians to hold this gentleman responsible was opposed to the facts of the case; and we note with pleasure the inspector's reference to him as "a man of unusual competence and zeal."

RAG-SORTERS' DISEASE.

SEVERAL cases of rag-sorters' disease having occurred in a paper manufactory at Ligat, in the Russian Baltic provinces, Drs. Schultz, Heerwagen, and Kranhals visited the place for the purpose of investigating the outbreak. They arrived there on April 30th, and learned from Dr. Radecki, the medical officer of the factory, that there had been fifty-six women employed in the rag-sorting room. On the 25th five were seized with the disease, and seven more on the 28th. Five cases had already proved fatal, one of them in twenty-four hours from its commencement. The symptoms of the disease were very similar in all the cases. In almost every instance it began with a rigor, the temperature rising very rapidly in some cases, but not in others; great depression and headache, however, following soon after the rigor —in all with increased frequency of respiration, distressing cough, thready pulse, and then a fall of temperature. After this the patient either rapidly improved or showed signs of collapse, with an imperceptible pulse and a subnormal temperature. There was no delirium, but the patient sank, collapsed and cyanotic. Death occurred on the average in less than three days. The post-mortem examination showed rapid decomposition and long-sustained rigor mortis. The green discolouration commenced on the chest and neck—not, as usual, on the abdomen. The mediastinum was engorged with serum or bloody serum; the bronchial glands were greatly swollen. Sanguineous serum was found in the pleural cavities and pericardium in considerable quantity. The blood was dark and watery; no signs of coagulation. The heart-muscle was pale and flabby, and the endocardium tumid. Nothing remarkable was found in the gastro-intestinal canal. The lungs were pale and dry and contained but little blood, the lower lobes being hypostatically congested, especially on the left side, but there was no pneumonia. The spleen was enlarged, its capsule easily torn, and the parenchyma nearly broken down. The committee of inquiry thought there was no doubt that the disease was of an infectious description, and that it was in fact "rag-sorters' disease." As considerable uncertainty exists as to the nature of this disease, some authors, as Klob and Frisch, believing it to be simply anthrax or charbon, while others, as Reihböck, look upon it as of a different nature altogether, every opportunity of investigating the subject should be taken advantage of. Dr. Kranhals, therefore, secured portions of the bodies and specimens of the serous fluids for the purpose of bacteriological and other researches. These had not been completed when the paper from which the above account is taken was read to the Riga Medical Society, but several observations of interest had already been made. Various bacilli were found, and amongst them some which appeared to correspond with Koch's "Malignant œdema bacilli." A small dog, too, into which some of the pleural fluid was injected, died on the third day with symptoms of malignant œdema, and the organs were found to correspond exactly in their post-mortem appearances with the descriptions given of that disease by Kock, Gaffky, and Hesse.

THE GUNPOWDER EXPLOSION IN SCOTLAND.

ON Sept. 25th an explosion of gunpowder on a large scale was carried out at the Crarræ Quarries, Lochfynside. It was intended to move some fifty thousand tons of granite, and for this purpose seven tons of powder were used for one blasting. The event was made one of interest for sightseers, and many persons went by steamer to view the "fireworks exhibition." After the blasting operation was complete a number of people entered the quarry to view the wonderful effects of the explosion, although a warning of danger appears to have been given. This, however, was either not heard or was unheeded. Those who first reached the interior of the quarry seem not to have experienced any special inconvenience, but those succeeding found themselves enveloped in a cloud of choke damp, and quickly showed signs of poisoning by the noxious fumes. In gunpowder explosions the gases chiefly evolved are carbonic acid, carbonic oxide, and nitrogen; but there are secondary products, some of which are compounds of sulphur. It may for all practical purposes, however, be taken that the unfortunate persons at the Crarræ Quarries were in much the same condition as regards the nature of the poisonous gases as those exposed to "charcoal fumes" in closed or ill-ventilated rooms. "One of the first effects of inhaling carbonic acid gas is to create an utter prostration of strength, so that even on a person awake and active the gas may speedily produce perfect inability to move or to call for assistance" (Taylor). In the accident now referred to, immense volumes of the gas must have been evolved, but owing to its confinement to a great extent in crevices, and to its high specific gravity, it moved slowly onwards, and in the absence of wind rose but gradually by diffusion. This explains how it was that the first groups of holiday people passed beyond the openings from which the gas issued, whilst those who followed came in for the full effect of the lethal vapour. But it was not merely carbonic acid gas, for, as we have said, in gunpowder explosions a considerable quantity of carbon monoxide is liberated at the same time. Thus the victims were suffocated from want of oxygen and directly poisoned by the toxic effects of the carbon monoxide. The symptoms were characteristic of the event. The sudden and complete powerlessness, delirium, convulsions, and insensibility were the precursors of death in several cases. The fact that both carbon oxides are practically free from smell helps to account for the suddenness with which the symptoms supervened. When the atmosphere is charged with sulphurous acid or sulphuretted hydrogen the odour serves as a warning on the early approach of the gas. Whereas, in the case of carbonic acid and carbonic monoxide the victim may be said to be enshrouded in the veil of death before he

Digitized by Google

is aware of his fateful position. It is matter of surprise to us that, considering the known danger from choke-damp of the gunpowder explosions in confined situations, even when ordinary blasting charges are used efficient precautions were not taken to avert so dreadful a catastrophe as happened at the Craræ quarries. The matter demands full investigation.

FORCIBLE AVULSION OF A FINGER.

M. AUCHÉ communicates to a Bordeaux medical society an account of a case of the rare accident of the complete avulsion of a finger. The patient was a carpenter, who, while engaged in lowering a heavy piece of timber by means of pulleys, got his finger caught between the rope and the block. By means of a sudden and violent effort he disengaged his hand, but left his third finger attached to the pulley. He felt but little pain, and there was no hæmorrhage. When seen by the writer some hours afterwards the wound was found to be tolerably regular, the skin-flap representing pretty closely the ordinary oval or "battledore-shaped" incision employed in amputating the fingers. From the centre of the wound the proximal fragment of the first phalanx projected. Disarticulation was then performed, and the wound, the edges of which could not be brought together, was left open and dressed with iodoform. The finger was afterwards examined. The skin was normal on the two distal phalanges, but excoriated in several places on the first phalanx, showing that this was where the finger had been caught. The external digital artery and all the nerves had been divided at the level of the wound, the internal artery having been divided higher up and its end hanging out nearly an inch beyond the torn surface of the finger. The phalanx was fractured at the junction of the distal and the middle thirds transversely but irregularly. The tendons were all left attached to the finger, those of the two flexors and extensor having been torn at their junctions with the muscular tissue and hanging out for several inches from the torn surface of the finger. The writer states that forty-two cases of avulsion of fingers have been previously collected by M. Polaillon. In none of them, however, was the severance complete. M. Farabœuf has demonstrated that a force of 150 kilogrammes (about 3 cwt.) is required to effect separation subsequently to fracture of the bone, and even then several sharp wrenches are needed, during which, of course the traction is very much greater than 150 kilogrammes. In this case the pressure of the rope on the finger against the groove of the pulley seems to have fractured the bone, and the sudden wrench given by the patient must have sufficed to tear the soft structures across.

THE KOREAN GOVERNMENT HOSPITAL.

FROM the first annual report of the work of this institution, which is situated at Seoul, the capital of Korea, it appears that since its establishment twelve months ago 10,460 out-patients and 265 in-patients, of all classes, and coming from all parts of the country, have been treated. Malaria is in Korea the most common cause of disease, and quartan ague the most common complaint. It is, however, worthy of note that while almost all the cases during the winter were quartan ague, those treated during the summer and autumn months were largely quotidian and tertian. Syphilis ranks next to malaria as a causative agent, and its effects are naturally numerous and varied. Of course, as is the case with all rice-eating nations, indigestion is prevalent. Leprosy is common, and skin diseases are seen in all varieties. In short, all the commonly known diseases are met with in Korea, with various modifications; and some uncommon ones, such as beri-beri, distoma, and filaria, are also known to exist. The native faculty, it appears, have some good ideas in regard to treatment. Their system is borrowed from the Chinese, and their medicines are legion. Acupuncture and the actual cautery are their chief remedies, and are the only surgery they attempt as a rule. Syphilis they treat with mercury, the drug being usually administered by fumigation. In March of the present year a school of medicine was opened under the hospital management, with sixteen scholars selected by competitive examination. After serving a probation of four months, twelve of these will be selected and entered regularly upon the course, the other four being dropped out. Each succeeding year twelve students will be appointed; they will receive board, lodging, and tuition, and after completing their course will enter the service of the government. Drs. Allen and Heron, under whose care the hospital is, are to be congratulated on the result of their endeavours to relieve the suffering Koreans and to provide a body of native physicians, who have been taught to disregard superstition and to treat disease by an enlightened and rational system. To the Korean Government, too, credit is due for the alacrity with which the scheme was taken up, and the liberality and official protection which have so much conduced to its success.

FOREIGN AND COLONIAL DEGREES AND THE NEW ACT.

IN view of the interest and importance of the clauses of the new Act referring to the recognition of Foreign and Colonial degrees, we have thought it desirable to procure the statement and opinions of a trustworthy member of the Bar. These will be found in THE LANCET of to-day. No nation is more impatient of the non-recognition of its own diplomas than our own, and none is more ubiquitous or more needs the advantage. We have something to gain, therefore, from a principle of reciprocity, which is one of the principles of the new Act. At the same time it is unpleasant to think that the Privy Council is empowered in certain circumstances to override the Medical Council, and insist on the recognition of degrees or persons of whom the latter disapproves. We protested strongly against this power of the Privy Council. One thing is certain, that in some countries, especially in America, medical education is very slight, and the tests of it very inadequate. We are not bound to recognise all the schools which any country chooses to permit.

MASSAGE AS A MODE OF TREATMENT.

THE *brochure* by Dr. Murrell on "Massage as a Mode of Treatment" expresses views which will be thoroughly endorsed by every observant and thoughtful physician. The author's story anent who should perform the massage forms an amusing exposition of the ignorance of what really constitutes the process. "A short time ago, in asking a medical friend if he used massage much in his practice, he replied, 'Oh yes, a great deal; my butler does it.' After that I should not have been surprised to hear the electrical treatment was conducted by his footman, and that the kitchenmaid undertook the obstetric cases." Skill in the proper performance of massage takes at least two years to acquire, and then it is necessary that the learner bring to his or her task a fair education and a certain amount of refinement, sound health, muscular strength, cheerful temperament, a soft and pliant but strong hand, and some acquaintance with anatomy and physiology. It is as absurd to suppose that "rubbing" or "shampooing" is massage, as it is to say that a daub of paint is a work of art. The duration of a sitting is another point on which the community requires enlightenment. On the principle that you cannot have enough of a good thing, the general impression is that each sitting should

Digitized by Google

last an hour. Twenty minutes should, on the contrary, be considered a long sitting. The physiological action of massage is a subject that still requires accurate investigation, but there is little doubt that it improves the appetite and nutrition of even healthy individuals. All those who wish to obtain some idea of the meaning of massage and its possible spheres of utility should read Dr. Murrell's pleasantly written book—a light task that will not occupy more than two hours of the busy practitioner's time.

"MEDICAL STUDENTS AT WORK."

IN an interesting article, entitled "Medical Students at Work," the *Graphic* of the current week gives particulars of the requirements of the medical profession, and points out the enormous field of knowledge now to be covered by the student of medicine. After discussing the curriculum, the writer touches upon the difficult question of the housing of medical students, and roughly divides them—as seen at the metropolitan hospitals, at least—into three classes: first, university men, a class which is, happily, on the increase; secondly, young men who, by serving an apprenticeship to a medical man or being themselves sons of members of the profession, have learned something of the bearings of their future career before entering upon it; and, thirdly, raw recruits shot out of country schools into the dangers and difficulties of the modern Babylon. It is this third class which is, undoubtedly, the most difficult to deal with, and a well-managed collegiate house is, beyond denial, a very desirable thing. A good likeness of Professor Bernays appears in "The Lecture in Chemistry"; and some other portraits are not difficult to trace. To members of, and those in any other way associated with, the medical profession the current number of our contemporary will be exceptionally interesting; and few St. Thomas's men will, we fancy, abstain from procuring a copy of an article in which their *alma mater* is so deservedly and gracefully honoured.

INFECTIOUS DISEASES IN LIVERPOOL.

A DIFFICULTY has arisen in Liverpool as to the isolation of infectious diseases. The Town Council have obtained the sanction of the Local Government Board to the creation of two separate hospitals, and the Netherfield-road Hospital, heretofore a private institution, has been transferred to them under a special Act of Parliament. It appears that the Corporation have undertaken to make certain alterations at Netherfield with a view to the better isolation of the different fevers, and also to acquire property around, so that there shall be an unoccupied zone of forty feet between the buildings and the boundary of the site. At the present moment the Corporation are informed that they may at any moment be without any accommodation for isolation; and it appears that although there are plenty of empty beds at Netherfield-road, yet they are not used because, in the opinion of Dr. Stopford Taylor, the institution is not in a sufficiently sanitary state for the reception of infectious diseases. As to this, he instanced statistics which go to show that the real mortality which has prevailed there during recent years is much in excess of that which apparently appears by the reports of the hospital committee. However this may be, the Corporation felt themselves in a difficulty as to advising that patients should be sent there in the face of the objections of their medical officer of health, and at the end of the meeting at which the matter was discussed nothing was done, it being hoped that there was no positive danger in immediate prospect. The unsatisfactory aspect of the question is that no present action is being taken in order to prepare the hospital for the reception of patients, and it was hinted that nothing would be done until the property in the immediate vicinity of the hospital has been acquired. We are not blaming the Sanitary Committee for their action as to this, because it may be that it is a condition of the use of the hospital that the forty feet zone shall first be provided. We could, however, have wished that, before the onset of winter weather, Liverpool, which has suffered so much from the lack of hospital provision for its infectious fevers, could have had some better prospect immediately in view; and it would have been some satisfaction to know that such internal alterations as are necessary to improve the sanitary condition of the place were at once to be commenced.

INOCULATION OF TUBERCLE.

Now that we possess a proof of the tubercular nature of a disease in the presence of the specific bacillus, the idea of communicability of the disease which was held by the older authors is capable of demonstration, and many cases have been recorded which leave little doubt that such an origin of the disease is far from infrequent. Among the latest cases of this kind is one related by Dr. Elsenberg in the *Berliner Medizinische Wochenschrift* for Aug. 30th, in which the disease was communicated by a curious custom which prevails among the lower classes of the Jews, of sucking the wound on the penis after the rite of circumcision has been performed. From this custom the author has often seen syphilis communicated, and latterly undoubted tubercle. Lindman recorded two and Lehmann ten cases in the *Deutsche Medizinische Wochenschrift*, in which it was thought that tubercle was transmitted from one to another in this way, and it is a noteworthy fact that Lehmann's ten cases were all produced by the same person, who shortly after died phthisical. The case which Dr. Elsenberg records was a child born in the month of September of perfectly healthy parents, which was circumcised on the eighth day and the wound sucked as usual under the idea of stopping the hæmorrhage and cleansing it; but instead of healing, as customary, the wound spread and formed an ulcer, the lymphatic glands became affected, and in the month of February the child was placed under the treatment of Dr. Elsenberg; but death ensued in the month of March, and in the tissue of the foreskin and glands tubercle bacilli were found by the Ehrlich-Weigert method. The next step to complete the observation was to examine the man who had sucked the wound. This at first disclosed nothing of importance, but it was found that he coughed at times and brought up some mucus; some of this obtained after prolonged coughing was examined, and found to contain bacilli.

AMMONIA APPLICATIONS IN MALIGNANT PUSTULE.

DR. LEONIDAS AVENDANO, of Peru, who has previously written (*vide* THE LANCET, Jan. 9th, 1886) in favour of the local treatment of anthrax by ammonia, now publishes in a Lima medical journal an account of a recent case of undoubted malignant pustule in which he successfully adopted this treatment. The patient was a married woman, aged thirty-four, who, two days after being stung by some insect in the forearm, began to experience the symptoms of acute inflammation in the spot. Thinking an ordinary boil was forming, she applied poultices. The next day, when seen by the writer, the pulse was 105, there was a great deal of œdema and redness about the arm, and there was a papule, which was blackish at the centre and surmounted with a circle of vesicles. The etiology, the rapid development, and the local symptoms all pointed to the malignant nature of the case. A crucial incision was made, and a brush saturated with the ordinary solution of ammonia applied to the cut surfaces. An acetate of ammonia and aconite mixture was ordered, and in a few days the patient was well. Dr. Avendaño thinks

Digitized by Google

that other caustics which have been employed in anthrax—as nitric acid, chloride of antimony, and Vienna paste—only partially and incompletely destroy the bacillus anthracis, but that ammonia has a much more powerful effect. This makes the fifth case in which he has seen remarkably successful results follow its employment.

MIDWIFERY STATISTICS IN VIENNA.

DR. KARL BRAUN has just published some very valuable statistics showing the improved and improving safety with which the patients in the first obstetrical clinic in the Vienna General Hospital have been delivered during several years past. He took charge in 1857, and during the twenty-six years following—i.e., to 1883—103,889 women have been confined in this clinic, which, it may be remarked, is only one out of three obstetric clinics in the hospital. Of these 1945 died, making the average death-rate for the whole period 17 per 1000. During the first six years there were 722 deaths out of 25,123 cases—i.e., 28 per 1000. The ventilation and warming arrangements were then altered in accordance with modern sanitary views, and various other hygienic improvements made, the result being that there was a decrease in the mortality during the next sixteen years, 1117 deaths occurring in 68,770 cases, or 16 per 1000. Since 1881 there has been a further decrease, owing to the use of antiseptics, &c., 15,000 cases in the last five years having resulted in only 106 deaths, or 7 per 1000. This improvement appears to be still continuing, as during 1883 the mortality was only 2 per 1000. During the whole period 7964 students received practical instruction in the clinic, the average number in each session or semester being 136.

AN UNUSUAL CAUSE OF DEATH.

ON Sept. 23rd, Dr. Thomas held an inquest at the Royal Free Hospital touching the death of Charles Atwood aged twenty-three years. Deceased was engaged, with an engine-driver, shunting trucks at King's-cross. As soon as the driver had passed the points held by Atwood, the latter was found to be insensible. Death ensued on the way to the hospital. There was no direct evidence to show that deceased had been struck by a buffer or other part of the engine or truck. At the post-mortem examination "one of the largest veins leading to the heart" was found to be ruptured, but there was no other sign of injury. The report of the evidence tendered at the inquest does not mention whether the lesion affected one of the pulmonary veins, the coronary vein, or either vena cava. In the absence of any statement regarding the existence of disease, we assume the vessel was healthy. It is well known that a person may meet his death from a severe blow or strain of the chest or abdominal wall, causing a trunk-vessel to give way, without there being any bruising of the part immediately struck. We know of a case in which the splenic vessels were torn through, the left renal artery ruptured, and the diaphragm rent from external violence, and yet the walls of the abdominal and thoracic cavities showed no sign of the physical violence to which they had been subjected. It is important in such cases to examine carefully for injury of the sternum, ribs, and spine, for it is possible to overlook a fracture where there is but little or no displacement. An instance occurs to us of death from hæmothorax caused by laceration of the vena azygos major. The body of a vertebra had been wrenched from the intervertebral substance, and the projecting edge of the bone had completely divided the vein. In another case the right subclavian vein was wounded by a fractured first rib, and here too the patient succumbed to hæmorrhage into the pleural cavity. We are not aware of spontaneous rupture of a large thoracic vessel having occurred in a young person in whom the tissues were normal in structure. Various pathological changes may so undermine the stability of a vessel as to render it unable to bear what may be termed physiological strain. Walshe cites a case of death from hæmoptysis consequent on rupture of one of the left pulmonary veins, but the pericardium was adherent and there was grave aortic valvular disease. The jury who investigated the subject of this notice returned a verdict in accordance with the medical testimony, adding that there was no evidence to show whether death was the result of injury or natural causes. From the facts at present before us we cannot help thinking that deceased received some injury during the shunting of the trucks, and this opinion, as we have shown, is consistent with the absence of any visible lesion other than that which obviously caused death.

ATAXIC PARAPLEGIA.

IN the current number of the *Archives de Neurologie*, M. Grasset of Montpellier concludes a paper on the subject of combined posterior and lateral sclerosis of the cord. The contribution is mainly one of a clinical character, and aims at throwing light on the symptoms of mixed varieties of myelitis. The author is of the same opinion as Dr. Gowers, that on clinical and pathological grounds the creation of a new name and separate consideration of the disease are desirable. M. Grasset proposes the term "combined tabes"—a name which is far less appropriate than that of ataxic paraplegia. But there seems to be some difference of opinion as to the range of symptoms. The English observer asserts that the lightning pains of true tabes are of rare occurrence in the combined sclerosis, whereas the French author states that, symptomatically, "combined tabes" is characterised by the association of symptoms of ataxic tabes (lightning pains, anæsthesia, motor incoördination) with symptoms of spasmodic tabes, &c.

THE CHAIR OF SURGERY IN QUEEN'S COLLEGE, BELFAST.

WE understand that his Excellency the Lord-Lieutenant of Ireland has recommended Dr. Thomas Sinclair to her Majesty for appointment to the Chair of Surgery in Queen's College, Belfast, in place of Dr. Gordon (resigned). Dr. Sinclair was a most distinguished student of Queen's College, where he obtained a very large number of prizes and scholarships, and at his final degree examination he carried off the gold medal. He has for some three years acted as Demonstrator of Anatomy and assistant to Professor Redfern. He is a Fellow of the Royal College of Surgeons of England, and at present occupies the posts of assistant-surgeon to the Royal Hospital, Belfast, and surgeon to the Ulster Hospital.

FALSE RABIES.

How long will it be ere it is properly recognised that every disease of the brain produced by inoculation of morbid matter is not rabies, however much the symptoms evoked may resemble those of the disease? Dr. Spitzka believes that he can produce rabies by the inoculation of any dirty matter whatsoever into the cerebral circulation. So thought earlier generations with regard to tuberculosis, but recent discovery has shown that tubercle can only be produced by the employment of specific matter. It seems to us that such confusion arises from a want of recognition of the fact that the signs of disease of the nervous system are as limited in number as the letters of the alphabet. Hence it happens that disease of any organ can be manifested only by the pathological signs peculiar to that organ. So that if disease, no matter what its nature, affect the medulla oblongata, the symptoms that arise might have a general likeness to those of rabies.

THE HOSPITAL FOR SICK CHILDREN.

THE winter session at the Hospital for Sick Children, Great Ormond-street, W.C., will be opened on the 6th inst. with a lecture by Mr. Timothy Holmes. The address will be delivered at 3.30 P.M. We have more than once spoken favourably of the efforts of hospitals like this to give instruction in subjects which students are apt to neglect, and it is to be hoped that the efforts of the medical staff of this institution to attract learners will prove successful, no course of instruction being likely to prove more useful or profitable to the future private practitioner than that on the diagnosis and treatment of the ailments of children.

ALCOHOL IN TEMPERANCE DRINKS.

SIR WM. HARCOURT raised a laugh against the teetotalers by insinuating that they liked temperance drinks very much in proportion to the amount of alcohol they contained. This seemed rather a libel on the pure tastes of the abstemious. Mr. A. W. Stokes, public analyst of St. Matthew's, Bethnal-green, has analysed samples of ginger beer and ginger ale, with a view to clearing up this matter, and reports finding as the largest amount 1·2 per cent. of proof spirit, and the lowest 0·2 per cent. Mr. Stokes explains that such an amount arises from the very manufacture of such drinks, and is an unavoidable result of the fermentation of the sugar. He well adds, a perfect non-alcoholic drink is still greatly needed. We congratulate our teetotal friends on such a vindication of their fair character.

OPEN SPACES.

No more important subjects were broached, nor any treated with more force and precision, than those of "Open Spaces and Physical Education" in Lord Brabazon's paper. The researches of Farr, showing, other things being equal, the direct relation of mortality to density of population, were powerfully used. It is becoming more and more clear that if London is to be maintained healthy, we shall have not only to keep the open spaces we have, but to create others. Lord Brabazon's labours have our heartiest approval.

BRAIN SURGERY.

WE understand that last Saturday Mr. Victor Horsley removed a large tumour from the brain of a man, aged thirty-five, who had been hemiplegic for some months, and comatose for three weeks. The tumour measured 3 in. in length by 2½ in. wide and 2 in. thick, and necessitated the removal of much bone in order to effect its complete extraction. The man has regained consciousness, and is free from the severe headache from which he suffered before he became comatose. Up to the present the patient continues in comparative happiness, and his wound has progressed so satisfactorily that it is perfectly healed. There has been also some recovery of power in the leg on the paralysed side.

BLOWS ON THE EARS.

CORPORAL punishment of some sort may occasionally be found necessary in schools, but, if so, it should be administered with due regard to the safety of the culprit. In a case recently reported, where a child of ten was slapped about the ears and shortly after showed distinct signs of chorea, we are not convinced that any serious injury was done. The muscular jerking so characteristic of chorea was markedly noticeable, it is true, after the chastisement, but similar signs are said to have been present in a slight degree before its infliction. The child was restless and had let her book fall. These are not necessarily proofs of disease, but they are somewhat characteristic premonitory signs of the nervous disorder which afterwards appeared in this case, and it is not improbable that such was their real meaning. Be that as it may, however, the mode of punishment was certainly irregular; and if it is in a measure excused by its lightness—for it was inflicted with the open hand,—it were clearly better not repeated. Teachers and others would do well to remember that permanent deafness has been caused by such a homely reproof as a box on the ear.

SIGNIFICANCE OF GLOBINURIA.

DR. KAMENSKI, in a dissertation for the Russian M.D. degree, has discussed the significance of globinuria in chronic inflammation of the kidneys. He finds that, as a rule, the quantity of globulin is in inverse proportion to that of albumen. When patients are put on milk diet the mean quantity of globulin passed in the urine is generally greater than when they are on a meat diet. Sometimes the maximum is attained the day following the milk diet. The practical conclusion arrived at by Dr. Kamenski is that the voiding of globulin in the urine is no sign of renal inflammation. With regard to the method of estimation, he prefers to collect the precipitate on a filter, and to examine the solution obtained from it.

DR. FREDERIC FARRE.

WE regret to learn that Dr. Frederic Farre, who was formerly, and for many years, Treasurer of the Royal College of Physicians, is very seriously ill. He was attacked with pneumonia about ten days ago, and his condition has become most critical.

THE MEDICAL SOCIETIES.

THE Obstetrical Society will hold its first meeting on Wednesday, Oct. 6th, the Clinical Society on Friday, Oct. 8th, the Pathological on the 19th, the Ophthalmological on the 21st, and the Royal Medical and Chirurgical on the 26th.

FROM the report of the examination made by Colonel Sir Francis Bolton of the water supplied by the several metropolitan water companies during the month of August, it appears that the Thames water sent out by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies exhibited no material change in quality from that of the July samples, the proportion of organic matter present being in every case, for river water, exceptionally small. The water drawn from the Lea and distributed by the New River and East London Companies contained rather less organic matter than any of the Thames waters. All the waters were clear and bright on delivery.

DR. MANSERGH, in the course of some observations he made at the recent Sanitary Congress on the water-supply of towns, appealed to his hearers to use their own efforts to keep their supplies of water clean. He was, he said, shocked at the way in which householders neglected to clean out their cisterns or reservoirs of water, in which leaves of trees and dead birds and mice are often found. Such neglect and thoughtlessness are, as Mr. Mansergh contended, perfectly disgraceful.

AT a special meeting of the Glasgow Southern Medical Society held on the 23rd ult., it was unanimously agreed to give a hearty support to Dr. James Morton's candidature as representative of the profession for Scotland in the General Medical Council.

SIR B. WALTER FOSTER has been nominated as one of the Foreign Vice-Presidents of the International Medical Congress.

Digitized by Google

THE death is announced of Dr. Georges Renson, *agrégé* of the Medical Faculty of the University of Brussels. Dr. Renson was a young observer of great promise, having published various contributions to the science of embryology, which he had studied under Professor Waldeyer at Strasburg, and the lectures on which had been delivered by him in Brussels for the last two years, acting for Prof. P. Heger.

DR. BRIDGES will lecture at Newton-hall, Fetter-lane, on Oct. 3rd, 10th, and 17th, at 8 P.M., on "Health, Physical, Mental, and Moral."

Pharmacology and Therapeutics.

ACTION OF TIN ON THE ANIMAL ORGANISM.

THE accidental poisoning by "tinned provisions," which has been attributed to the formation of stannous or stannic salts, has induced Dr. T. P. White to investigate the subject experimentally (*Pharmaceutical Journal*). The conclusions arrived at are: that tin has a direct irritant action on the intestines, increasing peristaltic movements; that it causes weakness, as the result of some action on the spinal cord; that it irritates some of the nuclei about the floor of the fourth ventricle, said to be shown in convulsive tremors and disorder of respiration; that the heart is not directly affected; and, lastly, that experiments with the metal, when acted upon by muriatic, acetic or "fruit" acids, were decidedly unsuccessful. It is therefore considered that tin, though possessing toxic properties when introduced into the blood, is devoid of danger when taken internally in any form that could result from contact with fruit or vegetables. Dr. White regards the cases of accidental poisoning as due to the solder used in sealing the can, or to impurities of arsenic, copper and lead in the tin itself.

ANTIFEBRIN.

Antifebrin, as the *Pharmaceutical Journal* points out, is a new antipyretic, that belongs to a very different group of chemical substances than those from which antipyretics have hitherto been drawn. The class of phenols has supplied us with carbolic acid, resorcin, hydroquinone, salicylic acid, and besides these are the bases like kairin, antipyrin, thallin, and quinine. Antifebrin is a neutral body, and identical with phenylacetamide or acetanilide, almost insoluble in cold water, but freely soluble in wine and alcoholic liquors. On dogs and guinea-pigs large doses seem to have no deleterious action. The subtance has been administered to twenty-four fever patients (the kind of fever is not mentioned) in doses of not more than two grammes in the twenty-four hours, and with such satisfactory results that a quarter of a gramme is said to be as effective in reducing the abnormal temperature as a whole gramme of antipyrin.

COLOMBINE.

M. Roux has observed the effect of pure colombine on fowls, the only animals which he has been able to get to take the medicine by way of the mouth. The symptoms produced by the ingestion of the poison were those that are associated with fatty degeneration of the liver and destruction of its working elements. Colombine irritates the intestinal tube, causing increased secretion from the gastric, intestinal, and biliary surfaces. The occurrence of these serious symptoms makes it necessary that the administration of the drug to human beings should always be in the form of small doses. The daily dose to commence with should not exceed one centigramme of the alkaloid and the powders of columba are to be preferred to the less certain alcoholic and ethereal liquid extracts.

ICHTHYOL IN RHEUMATISM.

Dr. Dubelir has been using ichthyol in the Moscow Military Hospital in rheumatic cases, both of an acute and chronic type, with success. This substance is obtained from mineral oil, and is rich in sulphur. It is applied, after careful washing and drying of the affected part, either in the crude form or as a compound sulphate of ichthyol and soda or ammonia, and at the same time is given internally in the form of drops or pills, the dose being from fifteen to twenty-five drops of the sulphate of ichthyol and ammonia, or a similar quantity made up into from six to twelve pills. In all cases the pain was relieved, but the swelling was not affected, so that the author thinks that the drug must only be used in the expectation of relieving pain. He warns his readers, too, that where the external applications are carried on for a long time, or without the necessary precautions of washing, a pustular eruption is liable to occur.

SPIRÆA FILIPENDULA IN HYDROPHOBIA.

A Polish medical man, Dr. Fürst Ignatz Jagell, who says he has for five and twenty years interested himself in the treatment of hydrophobia, declares in a Russian Journal that during that period he has treated 88 persons who had been bitten by rabid dogs or wolves. 26 of the patients having already commenced to exhibit the early symptoms of hydrophobia. Notwithstanding this, however, he did not lose a single case. They were all treated with the same remedy—viz., an infusion of the cortex of Spiræa filipendula (dropwort). It is needless to say that Dr. Jagell does not approve of Pasteur's proceedings; but how is it that we have not heard of his own remarkable success before? The plant he uses is not entirely unknown to pharmacy, the root and the leaves being sometimes employed, and believed to have astringent and diuretic effects.

SQUILLS IN WHOOPING-COUGH.

M. Nettier, of Nancy, has treated a number of cases of whooping-cough with simple oxymel scillæ, which he observes, ought to be ascertained to be good, as specimens to be found in pharmacies are of very different qualities. He advises the entire abandonment of cough syrups, and gives the squill even when there is diarrhœa and a good deal of vomiting. In the case of children who do not expectorate he even adds emetic drugs to the squill. He has seen cure result from this method of treatment in a few days, cases of failure being very rare. A colleague of M. Nettier, M. Remy, corroborates his statements, and says he has seen cases that have been going on for weeks yield to oxymel scillæ in a few days.

ULEXINE.

It is curious that the common furze, or Ulex Europæus, should have been found to yield an alkaloidal substance; for it has been so frequently examined chemically in order to ascertain its nutritive qualities that one would have thought an active alkaloid could not have escaped detection. However, Mr. Gerrard has extracted an alkaloid that is very soluble in dilute hydrochloric acid, forms long oblique prismatic crystals, readily soluble in chloroform, and giving with ferric chloride a deep-red colour. The physiological action has not yet been worked out, but it has been found that the alkaloid has a paralytic action on frogs.

TRIBROMIDE OF ALLYL.

This compound, which has been known to the chemical world since 1857, has been found to be of value in medicine, in the treatment of hysteria, infantile convulsions, angina, and asthma. Dr. de Fleury administers it in five-minim doses enclosed in capsules, from ten to twenty minims being taken by the mouth in the twenty-four hours; the drug may be injected under the skin in doses of from two to four drops dissolved in one or two cubic centimetres of ether.

REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.

[FIRST NOTICE.]

THE volume which Dr. Buchanan has just submitted to the Local Government Board bears the title of a "Report and Papers on Cholera," and it treats exclusively of that disease, and on the action taken in this country with regard to it. It brings our knowledge of cholera, in its various bearings, up to current date, and hence it may regarded as forming, not only an official report, but a valuable handbook on the subject with which it deals. The so-called report occupies only a small portion of the volume, and in this part Dr. Buchanan gives a summary of the various papers which make up the Appendix, bringing out in relief the principal lessons to be learnt from them.

Tracing, in the first instance, the course of cholera in

Digitized by Google

Europe since it first appeared in the southern ports of France in the summer of 1884, Dr. Buchanan calls attention to an exhaustive history of the course of the epidemic which has been prepared by Dr. Thorne Thorne. This history is very complete, and being largely based on official data received by Her Majesty's Government from consuls and foreign governments, it may be regarded as supplying authentic information, statistical and otherwise, of the epidemic of 1884-86. Some portions of the history are of especial interest—such, for example, as include details of the course of cholera in Gibraltar, in the various districts of Naples, and in other special localities. The results of the International Sanitary Conference in Rome are next dealt with, and attention is called to a paper on this subject prepared by Dr. Thorne Thorne, one of the British delegates; the paper, including a lengthened tabular statement of the results arrived at by the three conferences of Constantinople, Vienna, and Rome, so contrived as to show without difficulty the similarity and differences between the views which were held at the several gatherings. This part of the report necessarily deals largely with the question of quarantine, and Dr. Buchanan has availed himself of the opportunity of setting forth distinctly what are the views held by British epidemiologists as regards the measures needed to prevent the spread of cholera in Europe. This exposition comes opportunely to clear up difficulties which some have experienced as to the relative value of sanitary works and quarantine restrictions. Dr. Buchanan, together with most observers of the behaviour of cholera in Europe, evidently agrees with his predecessor, Mr. Simon, in regarding cholera as a disease which does admit of importation, and therefore of looking upon quarantine measures as useless and injurious, mainly in so far as they are shown by experience to be certain of failure, and because they take the place of the infinitely more valuable means of prevention which are to be found in an effective sanitary administration. In dealing with this subject he appears specially to guard himself against expressing views as to the behaviour of the disease in other than European climates; and he would doubtless not wish to imply that cholera is limited, in its means of spread, in the valley of the Ganges in the same way as it has always shown itself to be controlled in the Thames basin, and indeed in Europe generally. This portion of the report may usefully be quoted *verbatim*:—"The views of England concerning cholera in Europe, obtained from her own experience and strengthened by what she can learn of other countries, are that for European communities which have secured their soil, water, and air against befoulment there is little or no danger of cholera, no matter though the disease be actually brought into their midst; whereas communities which have not obtained this result have to encounter an unknown and serious measure of risk from cholera when it chances to be introduced among them. English medicine holds that cholera in Europe has at times a power of spreading from the sick to the healthy, exerting this power in the presence of filthy local circumstances, and most effectively where sources of drinking water have got contaminated by discharges from cholera patients. England puts her trust in measures that shall secure purity of earth, of water, and of air; and regards this purity as sufficient to prevent the spread of cholera in a European community. And as the measure that shall protect herself and other countries from such danger as attaches to intercourse with already infected places and communities, England relies, and exhorts other countries to rely, upon this same purity of local surroundings as the means for rendering that intercourse inoperative for harm. Accordingly, England imposes no restriction upon intercourse between one community and another—town and town, or nation and nation. She is content with providing for the care of persons actually sick, and with obtaining the destruction of whatever may be harmful in the discharges from cholera cases: for the rest, she is satisfied that each community, at all events under European conditions, can, if it pleases, render cholera harmless for itself, by the adoption of practices which are profitable against other diseases as well as against cholera. She would dispense, in land and sea traffic alike, with those detentions known as quarantines, having found them in practice to result rather in hazardous concealments and evasions than in any effectual exclusion of cholera."

The views here expressed as to the attitude of this country are well enforced in a passage in Dr. Thorne's report on the proceedings of the Rome Conference, where he shows that since England finally abandoned all attempt at quarantine, after the meeting of the Vienna Conference, she has spent an average of 6¼ millions sterling per annum in sanitary works, in addition to 2½ millions for current sanitary expenditure; and these sums take no cognizance of loans raised under the Artisans and Labourers' Dwellings Acts; or of the cost of many public works, as of water supply, defrayed by private companies; or of the salaries of sanitary officers; or of the large loans and current sanitary expenses of the metropolis. And again, it may be noted that this expenditure has been a voluntary one on the part of a people who trust to the results of such works rather than to the costly and injurious quarantine measures elsewhere, resulting from uncontrolled panic. Having regard to these facts, Dr. Thorne was right in maintaining at Rome that the substitution of the system of quarantine, which the majority of the delegates wished to enforce in this and other countries, in replacement of the system of sanitary administration which has been elaborated in this country, could only have a disastrous effect; and he had a right to protest that England had, by her expenditure, shown a belief in the efficacy of her system which no other country had shown as regards preparations for isolating those who must be detained under quarantine restrictions.

THE LEAVESDEN SCHOOLS.

THE following is the report of Dr. Bridges to the Local Government Board on the condition of the above schools:—

PREVALENCE OF OPHTHALMIA AND CUTANEOUS DISEASE AMONG THE INFANTS.

I visited this school on July 23rd. Major Jordan, in his report of July 5th (annexed) calls attention to the number of children under treatment, and appends a copy of a report of a sub-committee of guardians, and of a letter addressed by the medical officer to the guardians upon this subject. The numbers in the schools on the day of my visit were as follows:—

In the body of the school	Boys, 264 Girls, 177 Infants, 76	517
In infirmary		105
In probation wards		17
Total		639

About five weeks ago, after the inspection of Mr. Holgate, 53 children were transferred from the infants' department to the boys' and girls' schools, so that up to that time the number of infants was very much larger than it is now. Further, of the 105 children in the infirmary the very large majority—about three-fourths, indeed—are infants. It may be taken, then, that not less than a third of the children now in the school are under the age of eight years, and of this number, which may be called approximately 210, an unusual proportion are below the age of five. Children of two to four years are separated from children of five to seven years. Of the former class, I found 19 in the body of the school, and there were 35 in the infirmary. I examined individually all the infants in the body of the school. A large proportion of them had "granular" lids. This means that they have either had active ophthalmia (with purulent discharge more or less severe) at some former time, or at least that they are very likely to have it on some slight irritating cause, as dust, east wind, &c. The existence of this symptom is a very sure sign of some unhealthy condition in the school.

Now, in the construction of the schools I can find no unsanitary condition at all adequate to bring about this state of things. The ventilation of the drains, disconnexion of waste-pipes, &c., has been recently seen to by a very competent sanitary engineer. A few minor changes for the better yet remain to be effected, but, on the whole, in sanitary construction this school is above the average. In position, in dryness of soil, &c., it leaves nothing to be desired. The water supply is excellent. There are spacious playgrounds, which the children are encouraged to use. The superintendent and matron appear to me to take great interest in their work. The medical officer appears to be a man of unusual competence and zeal. The dietary of the children is sufficient in quantity. I was told that it was proposed to render it more variable; this will be a good thing; but I do not think that the dietary, as it stands, has

Digitized by Google

very much to do with the present state of the infants' department of the schools.

There remains, however, one unfavourable condition which in my opinion is amply sufficient to account for it—viz., overcrowding of the infants' dormitories, and, to some extent, of their day rooms also, throughout the winter and spring. The dormitory for infants at 5 to 7, holds at the present time 70 single beds, giving 30 feet superficial of floor space for each child. But a few months ago this dormitory held 60 double beds—i.e., not very far from double the number of children. This state of things was eminently calculated to favour the growth of ophthalmia and cutaneous disease, especially among very young children. This has, in fact, been the result.

I saw every child in the infirmary. Most of the cases are exceedingly slight, and some medical officers might have been disposed to treat some of them in the body of the school. But, considering all the circumstances, I think that Mr. Clarke is right in being very cautious as to the isolation of all cases that might propagate disease to others. The Infirmary, with its annexe for infectious cases, is an airy building, but each part is so connected with the other by corridors that effective isolation of separate classes is somewhat difficult.

On review of the whole case, I think that the guardians should consider the expediency of making some provision for certain classes of their children elsewhere than at Leavesden. The number during the winter approached seven hundred, a hundred more than the schools were built for.

THE RESPIRATORY MOVEMENTS AND THEIR INNERVATION IN RABBITS.

DR. MAX MARCKWALD has recently published the results of a long series of researches on the respiratory acts and the nervous centres connected with respiration in rabbits, in Kühne and Voit's *Zeitschrift für Biologie*, and the conclusions at which he has arrived are summed up in the following propositions:—1. The centres for respiration lie in the medulla oblongata, in intimate relation with the nucleus of the vagus. These centres are an inspiratory centre and an expiratory centre, the latter being stimulated with greater difficulty than the former. In normal respiration the inspiratory centre is alone called into play, and the expiratory centre only occasionally acts. 2. There are no respiratory centres occupying a higher position in the nervous axis. All the phenomena which have been considered to demonstrate the existence of such centres may be regarded as centripetal stimulations of the medulla oblongata acting reflectorially on the respiratory centre in the fourth ventricle. The mode in which encephalic dyspnœa occurs and disappears is directly opposed to the existence of centres occupying a higher position. 3. The central paths for respiration alone run in the cervical spinal cord; special centres for the respiratory acts do not exist in it. 4. The respiratory centres in the medulla oblongata are both automatically active and susceptible of reflex stimulation. 5. The automatically acting centre can only liberate respiratory convulsive movements, but no regular rhythmic respiratory movements. 6. Normal rhythmic respiration is a reflex act, essentially liberated through the nervi vagi, which prevent the tensions accumulating in the centre from becoming excessive, and convert the inherent stimulations of the respiratory centre into regular respiratory movements. 7. The vagal nerves are constantly being excited, possess a tone, and are sufficient during absolute rest of the animal organism to constitute the exclusive regulators of the respiration. 8. The superior central paths are, next to the vagi, of great importance for the liberation of regular rhythmic respirations. They are in a condition to cover any deficiency on the part of the vagi, just as the vagi can compensate any deficiency of the superior paths. Even in sleep—as, for example, in the hibernants, or after certain narcotics—the reflexes from the superior paths upon the respiratory centre remain operative. 9. If a portion of the superior paths are defective, whilst the vagi are still in working order, periodic or Cheyne-Stokes' respiration occurs. 10. No change in the excitability of the respiratory centre is requisite for the establishment of periodic respiration. The respiratory centre can be excited to the same extent with weak stimuli during periodic respiration, both during the attack and during the pauses. 11. The sensory cutaneous nerve cannot act vicariously either for the central paths or for the vagi. 12. Whilst the cutaneous nerves in animals, otherwise intact, exert little or no influence upon the respiratory centre, any influence they do possess increases remarkably after abolition of the central paths. Cutaneous reflexes under these circumstances may liberate a whole series of respiratory movements. The cutaneous nerves possess no tonus. 13. The centripetal nerves, which inhibit the liberation of respiratory movements, such as the fifth pair, the superior laryngeals, and the glosso-pharyngeals, possess no tonus, and must be regarded as accessory nerves of respiration, which are not implicated in normal respiration. 14. Stimulation of the fifth pair and superior laryngeal nerves, as well as of the olfactory and splanchnics, retards the respiration, and ultimately arrests it in the condition of expiration, whilst the glosso-pharyngeals have no influence upon the frequency of the respiration. The action of the glosso-pharyngeals is always to inhibit the respiration, and in that phase at which the stimulus is applied. 15. The respiratory centre cannot be excited by a simple electric stimulus, but requires to be supplemented by other intracentral chemical stimuli. 16. The shortest observable movement which the respiratory centre can emit sends to the phrenic nerves four effective simple stimuli, at an interval of about one-twentieth of a second. 17. The normal stimulus of the respiratory centre is not dependent upon the blood, neither upon the want of oxygen, nor upon the excess of carbon dioxide in the blood. Animals can continue to breathe alike without circulation and after bleeding for a long time. 18. Neither can the Hering-Breners theory of respiration be correct, since rhythmical respiration may persist after opening of the pleural cavity, and even after extirpation of the lungs. 19. The stimuli which act upon the respiratory centre are possibly of the same nature as those which excite the isolated heart, and are perhaps products of disintegration of the intercellular plasma. 20. Moreover, apnœa has nothing to do with the gases of the blood, but depends probably upon the removal of the stimuli stored up in the centre by the tonised vagi. The apnœa which occurs after section of the vagi is consequently very severe, and only persists for a short time. 21. So long as apnœa lasts no respiratory movements can be liberated either by direct stimulation of the medulla oblongata or of the central vagi. 22. The respiratory centre of the fœtus in utero is in a condition of diminished excitability. 23. When during delivery central or peripheral stimuli have once excited respiration, the centre suspends its action with difficulty, and the respiratory acts proceed rhythmically and regularly. 24. Various phenomena, such as the common salt dyspnœa, cold dyspnœa, and perhaps heat dyspnœa, render it probable that stimuli proceed to the phrenic nerves directly from a motor centre in the cerebral cortex, without implication of the respiratory centre. 25. The presence of sensory fibres in the phrenics supports this view, as does also the extremely delicate muscular sense of the diaphragm. 26. Rabbits at the age of four or five months are capable of living after section of both phrenics; younger animals die from want of air in consequence of insufficient expansion of the thorax.

SANITARY INSTITUTE OF GREAT BRITAIN.

THE business of the ninth annual Congress was resumed at York on Sept. 23rd, in two sections.

In the Preventive Medicine Section, Mr. Louis Parkes read a paper on "Milk and Disease"; Mr. J. Oakley read a paper on "The Prevalence of Defective Eyesight," in the course of which he advocated that especial attention be given to infants and children; the Rev. J. Malet Lambert followed with a paper on "Sanitary Associations, their Mission and Methods of Action"; and Mr. Sykes, the hon. secretary, read a paper on "The Medical Treatment of the Working Classes," which had been forwarded by Mr. W. Bousfield, chairman of the Metropolitan Provident Medical Association, after which the proceedings of the section were brought to a close.

Digitized by Google

In the Engineering Section, the President, Mr. Baldwin Latham, gave an address upon "The Probable Influence of Ground Water on Health"; Mr. E. C. Robins read a paper by Professor H. Robinson on "River Pollution"; Mr. Alderman Rowntree read a paper on "Municipal Government in relation to Public Health"; Mr. T. H. Harrison gave an account of an investigation into the classes who administered the Public Health Act; and Mr. W. Tattersall read a paper on "The Ventilation of Factories and Workshops," at the conclusion of which the sitting of the section was adjourned until the following day.

On the 24th ult., the Chemistry, Meteorology, and Geology Section met, Mr. Whittaker, who presided, delivering an address. Lieutenant Smith afterwards read a paper, which had been written by Lord Brabazon, who was unable to be present, on "Open Spaces and Physical Education." A discussion on the points raised was initiated by Mr. North, and carried on by Surgeon-Major Black, Surgeon-Major Pringle, Mr. C. Roberts, F.R.C.S., Alderman Rowntree, Mr. Symons, Dr. Ewart, Alderman Rymer, and the Chairman. Mr. C. Roberts then read a paper on "Medical Climatology." A discussion ensued, in which Mr. Symons, Mr. Clarke, Surgeon-Major Black, Surgeon-Major Pringle, and Professor Hope took part. Papers were also read by Dr. Percy Frankland on "Filtration of Water for Towns;" and by Dr. R. T. Cooper on "The Sanitary Condition of the Country Water Channels"; and Surgeon-Major Pringle gave an explanation of his system for the collection and storage of rain and drinking water.

In the Engineering Section, the proceedings of which were continued from the previous day, Mr. J. B. Bass read a paper on "American Sanitation," and Mr. J. V. Edwards one on "The Sanitation of our Dwellings." A discussion followed on these papers, and also on the one read the previous afternoon by Mr. Tattersall, on "The Ventilation of Factories and Workshops." Remarks were made by Mr. S. C. Robins, Mr. Tarbottom, Mr. Rogers Field, Mr. Darling, Mr. Harrison, and Mr. Hill, after which a vote of thanks to the readers of papers concluded the business of the sections.

The closing general meeting of the Congress was held in the evening, Sir Spencer Wells, Bart., in the chair. He expressed the satisfaction everyone connected with the Congress felt at the reception they had met with at York, and hoped that more attention would be drawn to sanitary matters. On the motion of the Dean of York, a vote of thanks was passed to the President, the Chairman, and Secretaries of sections. Prof. De Chaumont acknowledged the compliment, and on the motion of the President, seconded by Sir Thomas Crawford, a vote of thanks was passed to the Lord Mayor of York and the Lady Mayoress. Thanks were also accorded to the local committee, after which Prof. De Chaumont announced that the council had accepted an invitation to hold the Congress at Bolton next year.

In the evening a public dinner in connexion with the Congress was held.

On the evening of the 25th the closing meeting took place, when about 1000 members of the working classes assembled to hear addresses. Canon Fleming occupied the chair, and was well supported on the platform. "The Artistic Side of Sanitary Science" was discussed by Mr. Robins; Dr. George Vivian Poore gave an address on the "Reclamation of Waste Lands of Gascony by Bremontier" (an abstract of which we give in another column); and Mr. James Mansergh spoke of the "Supply of Water to Towns."

The Congress has been a highly successful one, about 150 members of the institute having attended the meetings, a larger number than at any previous congress, including three-fourths of the members of the council. The amount of interest taken in the gathering by the professional men of York and the neighbourhood is shown by the fact that nearly 200 associates' tickets were taken. The attendances at the sectional meetings have been very large—sometimes as many as 150; and the opening of the Health Exhibition took place in the presence of about 700 people. On the 25th ult. a number of the members of the institute spent the day in inspecting the sights of the city. The cathedral was visited in the morning; and a concert, given by the pupils of the Yorkshire School for the Blind at that institution, was attended by a small party. In the afternoon a visit was paid to the works of the York New Waterworks Company at Acomb.

BREMONTIER.

DR. POORE has done no more than justice to a very great but little-known sanitarian by choosing the work of Bremontier as the subject of his address given at the Sanitary Congress at York. The reclamation of the "Landes," a tract of country considerably larger than any English county except Yorkshire, ande the conversion of this district from a pestilential swamp into a most profitable forest, must certainly be ranked amongst the greatest sanitary triumphs which the world has ever seen. Bremontier's work is worthy of study also because of the extreme simplicity of the means employed, the absolutely insignificant amount of capital required, and the complete success which has been attained from the double point of view of both health and wealth. Bremontier saw that the only way to fix the dunes along the shore of the Bay of Biscay, and thus render the "Landes" behind the dunes drainable and cultivable, was to plant trees on them, and he succeeded in showing that by the exercise of a very moderate amount of care and ingenuity the Pinus maritima could be made to take root and flourish along the very margin of the sea. His first plantings were made in 1789, and by the dawn of the present century he had sufficiently demonstrated the practicability of his plans to warrant the French Government, at the instigation of the first Napoleon, to take up and continue the work. The result is known to all who have visited Bordeaux, Arcachon, and Biarritz. A province has been reclaimed, the inhabitants are no longer obliged to stalk on stilts through interminable swamps, malarious disease and pellagra have almost disappeared, and on the dreary sand wastes has arisen a vast forest of pine trees, yielding an almost inexhaustible store of timber, resin, and other products. The demands on our space prevent us from giving all the interesting details of the "story of Bremontier," as set forth by Dr. Poore in his address; but the concluding paragraphs seem worthy of being given at length for the benefit of our readers:—

"You will be asking, perhaps, why I have chosen this subject for my short address to the inhabitants of York, and, having listened to my tale, you will be asking for the moral. I chose this subject for my address for several reasons. The chief reason, probably, is to be found in the fact that I spent part of the early spring of this year in the district which I have been describing, and what I saw there made, as it could not help doing, a very deep impression upon me. My next reason was that it is an aspect of sanitation which is not often dealt with at meetings like this, and I was glad of the opportunity of taking you away from pipes, traps, sinks, and those expensive roads to health which we have to consider in cities, to contemplate the sanitary effect of good husbandry in the open air, and to show you on a large scale what I believe to be universally true—viz., that the cultivator of the soil must always be the right-hand man of the sanitarian. It has been refreshing for us to contemplate a sanitary work which has been a financial success. Sanitation always gives us the best of all dividends—health. And it is a short-sighted policy, especially in cities, to look for a money return on the capital expended on works for improving the public health. The thrifty French, however, have given to the world a valuable example of a comparatively small expenditure yielding *in the course of time* a magnificent return of both health and material prosperity.

"Do not run away with the idea that the Pinus maritima is a cure for all waste lands and unwholesome districts because it happens to be especially suited for the soil and climate of the eastern shores of the Bay of Biscay. In the warm climate of the south it yields abundance of resin and turpentine, grows quickly, and furnishes a large quantity of timber. In more northern climates it will grow, but does not flourish; and although there is at least one fine specimen in Kew Gardens, it is not, from all I have heard, a tree suited to this climate.

"My story seems to show that in the reclamation of waste lands we must not be in a hurry. Nature is sure, but, from our point of view, slow. Bremontier, and those who worked with him, began in a small way. We may be sure that experience had to be bought at more or less expense, and it was not until the success of his methods had been proved that the French Government seriously took the matter in hand. Bremontier was a true patriot. He worked

Digitized by Google

olely for the good of his country and for posterity. He had no idea of immediate profit, either for himself or his contemporaries. He drew his modest salary as inspector-general of roads and bridges (for he was an official of the state department of *Ponts et Chaussées*), but looked to no further profit. He lived barely long enough to see the resin flow from his first plantings. He pointed out, as it were, the way to the promised land, but, for himself, he only saw the promised land 'in his mind's eye.' It is good for us to bear this fact in mind, for many reformers of the present day seem, in questions of land management, to look only for immediate results, and to be actuated by the not very noble sentiment of 'Bother posterity—what has posterity done for me?' There has been a good deal of talk of late about the reclamation of waste lands in this country, and the opinion of some seems to be that worthless soil presents a glorious opportunity of wasting money. These are questions concerning which I cannot speak to you as an expert, but it seems certain that the problem of reclamation must differ with the circumstances of soil and situation, and that it is far more easy to do the wrong thing than the right. The first thing necessary is to find a Bremontier to show the way. We shall want a Bremontier to show us the way out of the pestilential quagmire which we Londoners are making, by dint of large expenditure, in the estuary of the Thames. We want a genius and an enthusiast who will do for the bogs of Ireland what this great Frenchman did for the 'Landes' of Gascony."

DR. JOSEPH ROGERS AND THE WESTMINSTER UNION.

AT a meeting of the Board of Guardians of the Westminster Union, held on Friday, the 24th ult., a letter was read from Dr. Rogers tendering his resignation of his appointment as medical officer of the Workhouse and Infirmary and public vaccinator of the Westminster Union, he being no longer capable of performing his duties, owing to continued ill health, whereupon the subjoined resolution was unanimously adopted, and a copy thereof was directed to be sent to him by the clerk.

"That this Board has received with much regret the letter just read from Dr. Joseph Rogers resigning the office of workhouse medical officer and public vaccinator for the union on account of his continued ill health, and while now accepting such resignation the guardians desire to convey to him their deep sympathy that he should thus be compelled to sever his connexion with the Board after many years of faithful service, and to record their high sense of the zealous and efficient manner in which he has discharged the duties of his offices, and for the warm interest he has at all times taken in questions affecting the proper treatment of the sick and infirm poor."

We heartily join in the expression of sympathy set forth in the above resolution. Dr. Rogers has, with great patience and courage, fought the battles of Poor-law medical officers under great difficulties and in the face of stolid opposition on the part of vestries and guardians, and his compulsory withdrawal from the field of his useful labours must be a matter of unfeigned regret to the whole medical profession.

THE LONDON HOSPITAL MEDICAL COLLEGE.

UPON the site of the old college attached to the London Hospital has sprung up a new and imposing building that bears no resemblance to the familiar structure it has supplanted. Of the original building nothing remains but the chemical theatre and laboratories, and certain unimportant rooms in the basement. The new building is about double the height of its predecessor, and in the place of the latter's dingy walls is a handsome structure in ornamental red brick. The old college was in size quite inadequate for its purpose, but so liberal has been the present "enlargement" that it will probably be the last of the many alterations the school has seen. The centre of the building is occupied by the museum, which is twice the size of the previous museum. From its galleries lead the pathologist's rooms, the physiological theatre, the histology room, the special rooms for physiological apparatus, and the physiological laboratory. The anatomical theatre is on the ground floor. Into it leads the lecturer's room, which is connected with the museum by a lift. In the lecture theatres straight rows of seats, with benches, have replaced the circular seats of the old building. The dissecting room is lit from the roof; the walls and floors are made of slate, and it is in connexion with the museum galleries, with the rooms assigned to the demonstrators, and with the prosector's room. A lift extends from the dissecting room to the mortuary and injecting rooms in the basement. Four practical class rooms have been added to the new building. The library is a particularly fine room; galleries run round two sides, and a handsome bay window has been thrown out on the side looking on to the hospital field. The stained glass and the elaborately decorated ceiling have been provided for by the liberality of the staff and other friends of the college. The new college provides a dining room for the students, with smoking and reading rooms, and the accessories of a comfortable club. The building is now ready for occupation, and furnishes a practical comment upon the progress of modern medicine.

THE HOSPITAL FOR WOMEN, LIVERPOOL.

A MEETING of members of the medical profession in Liverpool was held at Dr. Imlach's residence, Canning-street, last Tuesday evening. Dr. Gee, ex-president of the Liverpool Medical Institution, who presided as chairman, said that this large and representative meeting of medical men had been called at the instance of several practitioners, engaged chiefly in obstetric and gynæcological practice, to consider the treatment of a patient who had been treated for hydatid mole in the Hospital for Women in a manner to which exception has been taken in one of the daily papers.

The Secretary, Dr. Glynn Whittle, read several letters of apology from influential members of the profession, regretting their inability to attend, and expressing their sympathy with the object of the meeting; also a letter to the editor of the *Mercury*, asking him to nominate a medical man to be present.

Dr. Imlach said that after the termination of the trial of "Casey *v.* Imlach" several letters appeared in the daily papers animadverting upon the treatment pursued at the Hospital for Women. One of these letters contained charges of so libellous a character that he felt bound, both in his own interest and that of the hospital, to institute proceedings against the writer of the letter and the publishers of the paper in which it was printed. The letter was read to the meeting, and Dr. Imlach then described the medical history of the case and the treatment adopted. The patient was admitted into hospital in August, 1885, suffering from severe and protracted uterine hæmorrhage. A hydatid mole having been diagnosed, the uterine cavity was emptied, and the usual treatment promptly adopted with a successful result. Unfortunately, the patient insisted upon leaving the hospital at an earlier period than was advised. She expressed her gratitude when she left, and Dr. Imlach heard nothing more of the case until the publication of a letter in the *Mercury* of August 18th last, in which her subsequent debility was ascribed to the treatment she had experienced in the hospital.

The hospital registers, charts, and other documents were examined by those present.

Dr. Armstrong, physician to the Lying-in Hospital, moved, and Mr. Cayzer seconded, the following resolution, which was supported by several gentlemen and carried:—"That this meeting, having heard Dr. Imlach's statement of the medical treatment of Mrs. Noble, the patient referred to in the *Mercury* of August 18th last, as treated in the Hospital for Women, and having examined the hospital books and other documents bearing upon the case, is unanimously of opinion that the treatment adopted was proper, and was carried out in accordance with recognised methods."

Dr. Williams then moved and Mr. Marsh seconded a second resolution to the following effect:—"That Dr. Imlach, having

Digitized by Google

the full confidence and support of this meeting, do, at its special request, withdraw from the further prosecution of the proceedings for libel against the *Liverpool Mercury*."

This was carried unanimously; and Dr. Imlach thereupon said that, since a resolution carried by so large a meeting, after a thorough sifting of the case, was worth far more than the gaining of an action for libel, he would have pleasure in carrying out their wishes in this respect.

The proceedings concluded with a vote of thanks to the chairman.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Diphtheria in Aylesbury, by Dr. GRESSWELL.—The town of Aylesbury has two of its sanitary needs well provided; it has an excellent water-supply from the Chiltern Hills, and its sewage is well disposed of at the outfall by means of the A B C system. Otherwise, all indicates sanitary shortcomings, and these are at times of a grave character. The sewer culverts are often of most imperfect construction, the old ones have no appliances for flushing or for proper ventilation, and even old-fashioned catch-pits, so fruitful a source of nuisance, may be found in them. Some of the slaughter-houses are so situated as regards dwellings as to cause serious nuisance, and the common lodging-houses need more attention as regards their bedroom accommodation. Old houses are unduly crammed together on area, some having no curtilage whatever; others, again, are very dilapidated and altogether unfit for habitation; ashpits, with festering contents in large quantities, may be found near houses; scavenging by the authority is inefficient; yards are filthy; house-drains are not properly disconnected; in-door water-closets are inadequately ventilated; the waterclosets have, in the majority of cases, no water laid on to them, the pans being foul; some privy vaults are connected with sewers, and house-drains are of such construction that rats can make their way by them into houses. Diphtheria has, off and on, prevailed in Aylesbury, and the disease has appeared fatally every year since 1881. Including other throat affections, some of which are certainly allied to true diphtheria; no year since 1858, when diphtheria was first registered as a cause of death in the town, has been free from such mortality. In 1885 there were 15 diphtheria deaths, and the disease continued into 1886. Between October 18th, 1885, and February 24th, 1886, there were at least thirty-seven households invaded; 92 persons were more or less affected, and of these 20 died. The disease has shewn itself mainly amongst those aged from one to fifteen years, and it has prevailed especially, although not exclusively, amongst the poor. Neither milk distribution, nor water, nor geological circumstances appeared to affect the incidence of the disease. But, on the other hand, the schools, did have a material influence on the prevalence. In thirty out of the thirty-seven houses attacked, the first sufferers were attending schools, the beginning being amongst the British school children, extension taking place to those of another school, the scholars of the two schools being in free communication. In each of the instances in which a person, otherwise than a child attending school, was first attacked in a household, there had been ample opportunity for contracting the infection from persons already suffering from the malady. In connexion with this spread, it is noted that there was a marked prevalence of sore-throat antecedent to recognised diphtheria, the affection being seemingly communicable from person to person. One thing should be prominently remembered, and that is that, whatever the immediate cause of the throat affections, the town of Aylesbury exhibits many of the very sanitary conditions so well known to facilitate the spread of infectious disease, and it is imperative that the sanitary authority should take action and deal with them promptly. The sanitary officers are reported to have made careful survey of the place, to possess a record of abundant shortcomings, and to have reported many of them to the authority. The ratepayers should see that they are so represented that the grave sanitary defects prevailing in the place are speedily remedied.

Diphtheria in the Wincanton Rural District, by Dr. PARSONS.—The principal places in the Wincanton Union were inspected by Sir Anthony Home, for the Local Government Board, in 1872, and he reported that enteric fever was rarely absent from the district. His visit does not seem to have benefited the rural district as it ought to have done, for the present report shows that many conditions calling for amendment still exist. The immediate cause of the recent inspection was the prevalence of diphtheria at Queen Camel, at Galhampton, and other places. Then, again, there was enteric fever in 1885 at Castle Cary. The report dealing with the several places inspected is very voluminous and complete. It describes fully all the usual sanitary circumstances of local village life and occupation, and it concludes by indicating the directions in which future sanitary administration should be carried on so as to prevent the prevalence of infectious disease. The provision of proper sewers, the remedy of defective house drains, the proper construction of privies and their systematic scavenging, the protection of water-supplies from pollution, and the reconstruction of dilapidated houses, are matters which are urged upon the authority. The need for bye-laws to control nuisances and to regulate buildings, as also the provision of means of isolation for infectious fevers, are advocated.

Scarlet Fever in the Hayfield District, by Dr. PARSONS.—This rural district lies partly in Derbyshire, partly in Cheshire, and scarlet fever has been reported as prevalent during the past few years. At one time almost every household in which there were children was invaded in Higher Disley, the propagation of the disease here and in Disley village being largely attributed to school infection, and to the habit which mothers have of carrying their children into the houses of neighbours where cases of the disease already exist. The sanitary officers appear to have done their utmost to cope with the disease, but in the absence of public means of isolation their efforts have not resulted in much ultimate benefit. Some years since the authority professed their readiness to provide some hospital accommodation, but the premises then in view are no longer available, and the authority now seem to think that without compulsory powers of removal such provision would be useless. In this view we believe they are mistaken, for no point has been more clearly established in the official report on the Use and Influence of Infectious Hospitals than the fact that a reasonably attractive hospital secures the admission of children even so young that it might have been thought useless to urge their separation from their parents. In many respects the district is shown to need more energetic sanitary action, and a series of recommendations is appended to the report with a view to the guidance of the authority in this respect.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5599 births and 3657 deaths were registered during the week ending Sept. 25th. The annual death-rate in these towns, which had been equal to 22·6 per 1000 in each of the preceding two weeks, declined last week to 21·0. During the first twelve weeks of the current quarter the death-rate in these towns averaged 20·4 per 1000, and was 0·9 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 16·0 in London, 17·7 in Bristol, 18·8 in Brighton, and 19·7 in Birmingham. The rates in the other towns ranged upwards to 31·8 in Portsmouth, 32·0 in Wolverhampton, 37·1 in Preston, and 43·7 in Norwich. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 1199 and 1132 in the preceding two weeks, further declined last week to 933; they included 724 from diarrhœa, 63 from "fever" (principally enteric), 52 from scarlet fever, 37 from whooping-cough, 29 from measles, 23 from diphtheria, and not one from small-pox. The lowest death-rates from these zymotic diseases were recorded last week in Birkenhead and London; and the highest in Preston, Hull, Portsmouth, Wolverhampton, and Norwich. Diarrhœa caused the highest death-rates in Hull, Wolverhampton, and Norwich; no fewer than 35 of the 77 deaths registered last week in the last-mentioned city being referred to this cause. The mortality from "fever" was greatest in Cardiff, Leicester, Newcastle-upon-Tyne,

Digitized by Google

Plymouth, and Portsmouth; from scarlet fever in Leeds and Salford; and from measles in Preston, Wolverhampton, and Halifax. The 28 deaths from diphtheria included 15 in London, 2 in Birmingham, and 2 in Manchester. Small-pox caused no death in London and its outer ring, or in the twenty-seven large provincial towns. No small-pox patient was under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had been 110 and 168 in the preceding two weeks, were last week 154, and 55 below the corrected average. The causes of 73, or 2·0 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Birmingham, Newcastle-upon-Tyne, Leicester, and in four smaller towns. The largest proportions of uncertified deaths were registered in Halifax, Salford, and Bolton.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·6 and 18·8 per 1000 in the preceding two weeks, further declined to 16·8 in the week ending September 25th; a lower rate than had been recorded in any previous week of this year. This rate was 4·2 below the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 11·8 and 12·2 in Greenock and Aberdeen, to 19·7 in Perth and 27·8 in Paisley. The 415 deaths in the eight towns last week showed a further decrease of 50 from the numbers in recent weeks, and included 43 which were referred to diarrhœa, 18 to whooping-cough, 9 to scarlet fever, 4 to "fever" (typhus, enteric, or simple), 2 to diphtheria, 2 to measles, and not one to small-pox; in all, 78 deaths resulted from these principal zymotic diseases, against 93 and 73 in the preceding two weeks. These 78 deaths were equal to an annual rate of 3·2 per 1000, which was 2·2 below the mean rate from the same diseases in the twenty-eight English towns. The deaths attributed to diarrhœa, which had been 57 and 45 in the previous two weeks, further declined last week to 43, of which 12 occurred in Glasgow, 8 in Edinburgh, 8 in Dundee, and 8 in Paisley. The annual death-rate from diarrhœa in the eight Scotch towns last week did not average more than 1·7 per 1000, whereas the mean rate from the same cause in the twenty-eight English towns was 4·1. The fatal cases of whooping-cough, which had been 20 and 11 in the preceding two weeks, rose again last week to 18, of which 16 occurred in Glasgow and 2 in Paisley. The 9 deaths from scarlet fever exceeded the numbers returned in the previous two weeks, and included 6 in Glasgow. The 4 deaths referred to "fever," of which 2 occurred in Perth, showed a decline of 2 from the number in the previous week. The fatal cases of measles and diphtheria were few, and differed but slightly from the numbers in recent weeks. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 72 and 65 in the previous two weeks, rose again to 65 last week, and exceeded by 6 the number in the corresponding week of last year. The causes of 67, or 16 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 25·9 and 27·5 per 1000 in the preceding two weeks, declined to 24·7 in the week ending Sept. 25th. During the first twelve weeks of the current quarter the death-rate in the city averaged 22·0; the mean rate during the same period was 18·9 in London and 17·7 in Edinburgh. The 167 deaths in Dublin last week showed a decline of 19 from the number in the previous week, and included 25 which were referred to diarrhœa, 3 to scarlet fever, 2 to diphtheria, and not one either to small-pox, measles, whooping-cough, or "fever." Thus 30 deaths resulted from the principal zymotic diseases, against numbers increasing from 18 to 39 in the preceding four weeks; they were equal to an annual rate of 4·4 per 1000, the rates from the same diseases last week being 2·9 in London and 2·3 in Edinburgh. The fatal cases of diarrhœa, which had increased in the preceding eight weeks from 1 to 29, were last week 25. The 3 deaths from scarlet fever showed an increase of 1, while the 2 from diphtheria corresponded with the number in the previous week. For the second time this year no death from "fever" was registered during the week. Nine inquest cases and 5 deaths from violence were registered; and 42, or more than one-fourth of the deaths, were recorded in public institutions. The deaths of infants showed a marked decline, while those of elderly persons exceeded the number in any recent week. The causes of 30, or 18 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet Surgeon William Hogarth Adam has been placed on the retired list, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets. Fleet Surgeon Archibald Grant Colquhoun has been placed on the retired list, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets.

The following appointment has been made:—Staff Surgeon Alexander Hood, to the *Scout*.

ROYAL NAVAL ARTILLERY VOLUNTEERS (London Brigade). Herbert Collier, Esq., to be Surgeon.

ARTILLERY VOLUNTEERS.—1st Cinque Ports: Otho Robert Travers, Gent., to be Acting Surgeon.—1st Orkney: Thomas Patterson Devlin, Gent., to be Acting Surgeon.

ENGINEER VOLUNTEERS.—1st Cheshire: Acting Surgeon Joseph Lamb resigns his appointment.

RIFLE VOLUNTEERS.—1st Volunteer Battalion, the Buffs (East Kent Regiment): Acting Surgeon C. G. M. Lewis to be Surgeon.

Correspondence.

"Audi alteram partem."

DIRECT REPRESENTATION OF THE PROFESSION ON THE GENERAL MEDICAL COUNCIL.

To the Editor of THE LANCET.

SIR,—As announced in the *British Medical Journal* of Saturday last, the three candidates chosen by a large majority of the Committee for Selecting Candidates for the Direct Representation of the Profession on the General Medical Council are Mr. Wheelhouse of Leeds, Sir B. W. Foster of Birmingham, and Mr. Ernest Hart of London. Since his nomination, Mr. Hart, who is abroad, has telegraphed, "gratefully declining" the nomination. The sub-committee have therefore resolved to adopt Dr. Glover of London as their candidate in the place of Mr. Hart, Dr. Glover having stood fourth on the list.

I feel it to be quite unnecessary to say anything in justification of the action of the committee in this matter. Formed on the widest basis, irrespective of place, circumstance, or numbers—gentlemen living in 164 towns having been applied to, and acceptances to serve having been received from 363 individuals—it cannot be accused of favouritism, no hint or suggestion as to the names to be selected having been given to any one of these 363 gentlemen. Neither can the action of this committee be considered a failure—a *fiasco*—when we look at the names which it has adopted as its candidates. That those names will commend themselves to the great bulk of the profession in England and Wales I feel assured, as it *cannot be by chance* that 363 gentlemen, living in 164 towns, have almost unanimously agreed to adopt them. The Committee feel that failure would indeed be a calamity for the profession, as no other organisation like theirs has been, or is likely to be, found; and in that conviction they will leave no stone unturned, and will spare no labour, to render their efforts successful.

The importance of sending up to the General Medical Council men of tried ability, with knowledge of affairs—men who have laboured in the interests of the profession, and who are in touch with members of every branch of it,—cannot be over-estimated. A mistake once made would not easily be remedied, and *prestige* and respect once lost would not soon be regained.

Mr. Wheelhouse, for nearly the whole of his professional life, has been an active member of the governing body of

Digitized by Google

the British Medical Association; he has been president of its Council, and in that capacity showed the greatest tact and zeal in the management of its affairs, to which he still gives the benefit of his ripe experience. He is a typical general practitioner, who has reached his present eminence by those arts which become a liberal-minded and honourable man. His place in the estimation of his brethren throughout the kingdom is sufficiently indicated by his place at the head of this poll.

Sir B. Walter Foster is widely known by his activity and zeal in the cause, not of one association only, but in that of the whole profession. It is owing to his strenuous exertions in Parliament that the very inadequate number of two direct representatives of the profession has been increased to three, for which he is deserving of substantial reward; and the best reward which can be offered to him is electing him as one of our representatives.

Of Mr. Hart's great exertions in the cause of medical reform too much could not have been said, had he decided to stand. Dr. Glover, who succeeds to his place on the list, is well known, to all those who have followed the course of medical politics, as an active worker in the way of medical reform; and as a member of the editorial staff of THE LANCET he has endeavoured to advance the interests of the profession in many ways. Dr. Glover is also intimately acquainted with the working of the General Medical Council, and will doubtless prove an ardent reformer of its abuses. All of these gentlemen are so highly respected and trusted by the profession, for whose interests they have so long striven, that it appears to be both right and proper that every member of it should use his best endeavours to secure their election. The committee I represent will not relax its exertions, feeling assured that, as they deserve success, so it will be accorded to them.

On behalf of the Committee,
I am, Sir, your obedient servant,
WILLIAM STRANGE, M.D., Chairman.

Worcester, Sept. 30th, 1886.

To the Editor of THE LANCET.

SIR,—I learn by telegram, received to-day, that I have been nominated, as the result of a ballot taken by the Committee on Direct Representation, at Birmingham, for election as a direct representative of the profession on the General Medical Council. Owing to the miscarriage of the post, I have not seen the recent numbers of the medical journals, and I am not therefore aware of what may have been the previous steps, or how it happens that the honour has fallen to me. I wish, however, with your courteous aid, at once to make it known in the profession that, while highly appreciating this mark of the confidence and favour of my professional brethren as one which I shall always treasure as a valued recollection, I am at present unwilling to accept nomination for election to the General Medical Council, and I have therefore requested that my name may be withdrawn. I am, Sir, your obedient servant,

Prague, Sept. 26th, 1886. ERNEST HART.

To the Editor of THE LANCET.

SIR,—In an article published in the *British Medical Journal* of Saturday last, respecting the action of a selection committee organised *at a small private meeting* held at the Grand Hotel, Brighton, the following passages occur:—This committee "was projected at an annual meeting of the Association, which was *of the most public character*" (italics mine); also, that "the circumstances of the establishment of the committee necessitated that it should be intimately connected with the name of the British Medical Association." So far from these statements being true, the reverse is correct, as follows:—The British Medical Association had the matter brought before its members at a general meeting at Brighton in August. They *declined to take any part in the selection or election of candidates.* No candidate or candidates have the right to make use of the name of the Association, or to pose as its nominees in any shape or form. I am, Sir, yours truly,

Harpurhey, Manchester, Sept. 27th, 1886. WM. ARMSTRONG.

To the Editor of THE LANCET.

SIR,—Having been present at the Birmingham meeting, it seems to me that Dr. Taaffe has well stated some of its defects. Only thirty-two attended on that occasion, and when the voting took place, at the termination of the proceedings, fourteen remained. In accordance with the resolution a voting paper was sent to the 343 who had replied to a circular sent by the secretary, and these are now dignified as a "committee for ascertaining the wishes of the profession collectively." This body professes to be simply an organisation to ensure facility in selecting candidates; yet its work has extended to this so-called ballot amongst its self-elected members, showing a majority in favour of the original nominees, of those who brought the matter before us at Brighton, when the Association refused to interfere in the election. No one would doubt the ability or fitness for office of those selected; yet it must be borne in mind that some intending candidates were not even proposed, no one present being acquainted with, or at any rate wishing to further, their candidature. In conclusion, this election has for its purpose the expression of the views of the profession as practitioners, and should in no way be biased by party influence; and to use the machinery of the Association as an agent in the matter is to act without authority and in direct opposition to the expressed wish of the general meeting this year. I am, Sir, yours &c.,

Sept. 27th, 1886. VERITAS.

To the Editor of THE LANCET.

SIR,—On the subject of the approaching election let me point out to provincial candidates the absolute necessity for being legally represented at the scrutiny of votes. It is simply astounding that the Privy Council should allow the Branch Councils, or rather their registrars, to go behind the Register. Add to this that the votes are not to be attested, and the absolute necessity for approaching the Privy Council, if need be, in order to ask them to insist upon the usual course being followed, of candidates being represented at the scrutiny, will be seen at a glance. I have addressed a formal communication on the subject to the Irish Branch Council. No man at the approaching election should be allowed to vote from behind the screen.—I am, Sir, yours truly,

Cashel, Sept. 26th, 1886. THOMAS LAFFAN.

*** Many other letters of a tone similar to that of the above have reached us, but want of space precludes their publication.—ED. L.

THE TREATMENT OF PELVIC HÆMATOCELE.

To the Editor of THE LANCET.

SIR,—The letter of Dr. Campbell Black in THE LANCET of Sept. 25th, on Subperitoneal Hæmatocele is interesting, and opens ground for discussion. He does not give any history of the tumour spoken of, and a doubt must exist as to its being subperitoneal. I have long been doubtful myself if pelvic hæmatocele is ever subperitoneal, and though this is very minutely described in the case recorded by Simpson, I am satisfied that in the post-mortem room there is almost insuperable difficulty in defining the serous layer of the peritoneum and differentiating it from the products of inflammatory action. I pointed out in the Ingleby Lectures in 1883 how experiments had convinced me that it is very hard to inject fluid in any quantity into the cellular tissue round the uterus post mortem, and that where blood exists in this locality it is in small quantity, and more properly comes under the category of thrombic.

I have the notes of twenty-seven cases of well-marked pelvic hæmatocele observed during some years past. In this number there have been four deaths, three of which at least I think were preventable. At some future time I hope to place these on record. In the meantime I may express my prior conviction that the majority of cases get well if left alone. The statistics of Voisin, West, Emmet, Hutchinson, Dolbeau, and others, emphatically prove this. Emmet, in speaking of puncture, goes so far as to say that "in a large majority of cases such interference would be criminal." The testimony of the late Dr. Thorburn, whose experience must have been extensive, is very decisive on this point. He says—"Every case of hæmatocele which I have seen for over twenty years (and they have been exceptionally numerous, though I cannot tabulate them), which did not die from immediate hæmorrhage, has perfectly recovered, with suppuration in only one instance."

I may point out that the puncture as mentioned by Nonat is very different from the aspiration of the present day, and

Digitized by Google

that Nélaton and others abandoned it as dangerous long ago. In certain cases aspiration is valuable for diagnosis, and in some, carefully practised, may aid in promoting recovery.

The question of the influence of the menstrual period in aggravating the condition, as quoted by Dr. Black from Nonat, is at variance with my own observation. I am of opinion that Voisin is more correct when he states the curious fact in connexion with recovery by resolution, that after the formation of the tumour recurrence of the menstrual period seems to exercise no influence in increasing its size; on the contrary, each period is marked by a notable diminution in volume, and that, instead of gradual decrease, it recedes by successive steps, which correspond with the catamenial periods.

I am, Sir, yours faithfully,

EDWARD MALINS, M.D.,

Sept. 1886. Obstetric Officer to the General Hospital, Birmingham.

To the Editor of THE LANCET.

SIR,—Dr. Campbell Black illustrates very well the state of confusion in the nomenclature of this accident. "Sub-peritoneal" and "retro-peritoneal" hæmatocele can of course only be varieties of "extra-peritoneal" effusion, and belong to the non-fatal class. It is the intra-peritoneal hæmatocele which requires surgical interference, on the principle of "cut down and tie the bleeding point." Such a case as that quoted by Dr. Black from Nonat is precisely an illustration of this. Nonat was the best diagnostician, I believe, we have ever had in gynæcology, but he lived before the days when the peritoneum could be opened without risk, and all his cases of ruptured tubes died, as all mine did before I operated on them. Dr. Black's case illustrates the extra-peritoneal hæmatoceles, which rarely require even to be punctured, and which nearly all get well. It is certainly not such cases as Dr. Black's for which I recommend operative interference, as he might have easily understood if he had read what I have said on the subject with more care.

I am, Sir, yours faithfully,

Liverpool, Sept. 24th, 1886. LAWSON TAIT.

TRIPLE QUALIFICATION OF SCOTLAND.

To the Editor of THE LANCET.

SIR,—Allow me through the medium of your columns to draw the attention of medical tutors to the fact that candidates for the first professional examination for the triple qualification are now required to produce a *six* months' certificate of Practical Anatomy, instead of *nine* months as heretofore. At my request the joint committee made this alteration in July last. A candidate, however, cannot present himself for examination until he has been nine months registered as a medical student; consequently he can devote the summer session to Practical Physiology.

I am, Sir, faithfully yours,

Dublin, Sept. 24th, 1886. CHAS. FREDK. KNIGHT, M.D.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

DURHAM UNIVERSITY.

AT a convocation of Durham University, held in Bishop Cosin's library, Palace-green, Durham, on Saturday last, the degree of Bachelor in Surgery was constituted, and the status of Licentiates in Sanitary Science, the regulations for which were approved.

THE NEWCASTLE TURKISH BATHS.

I daresay we have in Newcastle one of the most complete Turkish Baths to be found in any provincial city; latterly, too, a Russian bath has been added to the premises. The late Sir John Fife did much by his work on "The Turkish Bath" to popularise its use in the north. Dr. F. C. Coley, of this city, has already published a pamphlet on the subject, and he is now, I am told, engaged on a more complete work on the Turkish Bath, which will soon be issued.

RATING OF SCHOOLS AND HOSPITALS.

The Rev. Dr. Rutherford, who is also a qualified practitioner here, at a late meeting of the guardians moved a resolution against departing "from the time-honoured custom of the non-enforcement of the rating law against hospitals, charities, public elementary schools, &c." The *Newcastle Chronicle* says: "The resolution was, with a slight alteration, carried unanimously, and, we should say, to the public satisfaction, because to burthen such institutions with rates is, as was pointed out, to hamper their management and to clog the fly-wheel; besides, the burthen of the ratepayers would in the long-run be made heavier by it. It was generally considered that the doctor's resolution made an end of the business. Not so, however. The Assessment Committee of five have decided to the contrary. They met after the last fortnightly meeting, and, in spite of the Board's resolution, assessed—not nominally, as was understood would be the case, but substantially—the schools. The public charities of the city, including the infirmary, are, we understand, also to be burthened with rates. Moreover, it would seem that in this matter the Assessment Committee, though presumably subordinate to the Board of Guardians, is omnipotent."

DEAF, DUMB, AND BLIND CHILDREN.

The authorities of the Newcastle Deaf and Dumb Institution have received official intimation that the Commissioners appointed to inquire into the maintenance of similar charities, and the amount of education &c. they afford, will visit the institution on Thursday next. The committee of the Victoria Asylum for the Blind have also received a similar intimation of intended inspection. Lord Egerton is the chairman of the Commission.

Newcastle-on-Tyne, Sept. 28th.

LIVERPOOL.

(*From our own Correspondent.*)

HOSPITAL ACCOMMODATION FOR INFECTIOUS DISEASES.

AT the last meeting of the Health Committee, the important subject of hospital accommodation for infectious diseases was again discussed. The matter has been repeatedly before the committee, the City Council, and the public for years past, but still remains a *quæstio vexata*. The difficulty is not far to seek. The new hospital, which is undoubtedly required, must be accessible, and yet not too near any dwelling-houses. This is the difficulty; the remedy is much less easily indicated. Dr. Taylor, the medical officer of health, having been asked to report on the question, submitted one, in which he gives the following table of the number of cases of scarlatina and fever which have come under his notice during the summer months of 1884-5-6:

	1884.	1885.	1886.
SCARLATINA.			
May	55	70	67
June	48	100	59
July	63	91	48
August	38	75	129
To 18th September	41	59	125
FEVER.			
May	94	46	24
June	63	65	43
July	56	44	31
August	51	63	54
To 18th September	41	53	47

To meet this very serious state of matters, which, if not met promptly, will soon become much more serious, the following was the hospital provision for non-epidemic periods in the city until recently:—Toxteth Workhouse Hospital, 50 beds; Mill-road Workhouse Hospital, 98 beds; Brownlow-hill Workhouse Hospital, 160 beds. Besides the above, there was Netherfield Institution, stated to be capable of accommodating seventy patients. Dr. Taylor proceeds: "At the present time there is only accommodation for a few cases of fever in the Brownlow-hill Workhouse Hospital. Toxteth Hospital is closed, so is Mill-road, and the Netherfield Institution requires alterations. The hospital at Brownlow-hill cannot long be continued for the reception of infectious disease, the building being required for the accommodation of paupers; and however wishful the Select Vestry may be to oblige the Corporation, their own necessities will compel them to refuse a lengthened occupation of their hospital for public purposes.

Digitized by Google

The only proposal so far submitted to the Council is the erection of a hospital with sixty beds, which will have to discharge the duty of the 308 beds at Toxteth, Mill-road, and Brownlow-hill, whilst Netherfield Hospital will accommodate few, if any more, patients after the alterations than before. The medical officer, after carefully considering the present position of the hospital question, and finding that a serious epidemic of scarlatina has commenced, without the provision of proper means of isolation, would strongly urge upon the Health Committee the necessity of immediately erecting some huts on a site in Kensington-fields, as being the most convenient of access from every part of the city, and the most eligible situation for a public hospital." Unfortunately, the Kensington-fields site has dwelling-houses sufficiently near to be prejudiced by the erection of a fever hospital, and with characteristic selfishness the property owners are crying out against a movement which threatens to deteriorate the value of their property. How the matter will end remains to be seen.

Liverpool, Sept. 29th.

GLASGOW.

(From our own Correspondent.)

REPRESENTATION OF THE PROFESSION ON THE GENERAL MEDICAL COUNCIL.

HERE, as elsewhere, this question is agitating professional circles. So far, the only candidate put up in the west of Scotland is Dr. James Morton, to whom a large amount of support has already been promised in and around Glasgow. The Glasgow Southern Medical Society, of which Dr. Morton is the oldest member, has declared unanimously in his favour, and his committee is large and powerful. Dr. Robert Sinclair of Dundee seems to find enthusiastic support in his own district, and as he is a Glasgow man and well known in the west of Scotland, he will no doubt receive many votes from this district also. As for the candidate nominated in Edinburgh, Sir Douglas Maclagan, there is everything to say for him and nothing to say against him, except one rather powerful objection, strongly felt here, that Edinburgh is already fully represented in the Council, and that, if he were elected, she would have four representatives, which is more than her just share. Dr. Bruce of Dingwall and Dr. D. Stirling of Perth are also understood to be before the profession as candidates, but, so far, very little has been heard from them; their friends do not seem to be working so energetically as those of the other candidates. Ultimately the vote will probably be territorial, and will turn, not so much on the merits of those nominated, as on the part of Scotland they are supposed to represent.

PUBLIC HEALTH.

At the last meeting of the Town Council attention was directed to an outbreak of scarlet fever in the east end of the city, more especially in connection with a particular dairy farm, from which no fewer than forty-four cases of the disease were known to have originated. Complaint was also made of obstacles being put in the way of the sanitary officials by the public in dealing with such epidemics; and the necessity for regular and compulsory notification of infectious disease was pointed out.

Glasgow, Sept. 30th.

IRELAND.

(From our own Correspondent.)

ROYAL UNIVERSITY OF IRELAND.

A ROYAL WARRANT approving alterations in the statutes of this University was published last week as a Parliamentary paper. The following are the chief alterations in the statutes:—To repeal the second paragraph of chapter 2, and to substitute for it the following: "No student who, previous to matriculating in this University, was or had been a student of any other university, shall be eligible to be awarded any of the exhibitions or other prizes of this University, save in some collegiate grade not lower than that which such student shall hold, or shall have held, in such other university; and the scholarships of this University shall be deemed to be prizes in connexion with the matriculation examination." To repeal paragraph 2 of chapter 4, section "Of medical fellowships," and to substitute therefor the following: "The Senate may from time to time appoint for each of the medical Fellows such salary as they shall consider proper, not exceeding £2000 a year, provided always that if any medical Fellow shall hold any fellowship or professorship in any other university, or any college attached to a university, or in any college endowed with public money, he shall receive in respect of his medical fellowship in this University only such sum (not exceeding the salary fixed for him by the Senate under this clause) as, with the salary of his other fellowship or professorship, shall amount to £400 per annum, being the sum hereinbefore fixed as the limit of the salary of Fellows of the University." By the decease of the Rev. Dr. Stevenson a second vacancy for a member of the Senate has taken place. The Crown has the right of nominating his successor.

BRITISH MEDICAL ASSOCIATION.

A meeting of the members of the Dublin Branch of this Association was held on the 24th ult., to consider a recommendation from the council of the branch, that the next annual meeting should be held in Dublin. Dr. Bennett presided; and the Rev. Dr. Haughton proposed, and Sir William Stokes, President of the Royal College of Surgeons, seconded, the following resolution, which was unanimously adopted: "That the Association should be cordially invited to meet in Dublin in 1887, and that the universities and the different medical bodies, as well as all members of the profession residing in Leinster, should be requested to join in the invitation." Dr. McDonnell, F.R.S., President of the Academy of Medicine, moved, and Dr. Finny seconded—"That in the event of the invitation being accepted, Dr. J. T. Banks, physician to the Queen in Ireland, Regius Professor of Physic in the University of Dublin, &c., be nominated President-elect of the Association," which was carried by acclamation. Sir George Porter, Surgeon in Ordinary to the Queen in Ireland, moved—"That the officers and council of the branch be authorised to make all necessary arrangements for the proposed meeting, and that a subscription list to defray the expenses thereof be now opened." This was seconded by Dr. Collins, Governor of the Apothecaries' Hall, and adopted.

DIRECT REPRESENTATION OF THE PROFESSION IN IRELAND.

A meeting will be held this week at the Shelbourne Hotel, for the purpose of nominating a committee to support the candidature of Dr. Kidd for the office of direct representative of the profession in Ireland on the General Medical Council.

SOUTH DUBLIN UNION.

The question as to the liability of the guardians to admit a person to hospital who is willing to pay for his support and treatment came before the Board of this union last week, and as there seemed a doubt on the subject, the following query has, on the suggestion of Sir J. Owens, M.D., been submitted to the Local Government Board: "If a sick person, not destitute, presents himself at the workhouse and requests to be medically treated, and claims to repay the entire cost of his maintenance therein according to the full average cost, can the master refuse his admission—has he any discretion in the matter?" Common sense would suggest that the medical officer who attends the case, if admitted, ought to be compensated for his trouble, as his appointment by the guardians only requires him to attend pauper patients.

Dr. Kearney has been elected medical officer of the Roundstone dispensary district.

Dublin, Sept. 28th.

EGYPT.

(From our own Correspondent.)

MEDICAL MISSION AT CAIRO.

UNDER this heading THE LANCET of August 21st mentions an appeal on behalf of Miss Whately's well-known and too little supported Mission. A few years ago it would have been accurate to write of it as the only agency "where gratuitous help and remedies are given to the poor"; but during the English occupation of the country other and

Digitized by Google

more important means have been provided. To Miss Whately's Mission Schools for children of both sexes and all nationalities has been for some years attached an out-patient dispensary, presided over by a Syrian doctor, and resorted to daily by dozens of the neighbouring poor. For this no Government grant is given. At Kasr-el-Aini Hospital there is now a monthly record of 4000 out-patients, averaging 150 daily except Friday. In addition to this free aid, the Government supplies to each of the twelve districts of Cairo an Egyptian or Syrian doctor, who is obliged to attend at an office in his quarter every day, and see any patients who come without fee. In the suburbs of the town, which are not thickly populated with natives, the attendance is very small, but in six of the crowded quarters there is a daily attendance of from twenty to fifty out-patients. Besides this, about 300 patients are seen, mostly gratis, every month at the out-patient department of the Deaconesses' Hospital in Cairo, and to this there has lately been added an eye department, which already attracts nearly 100 patients a day.

STREET SCAVENGING IN CAIRO.

No less a sum than £18,000 a year has hitherto been expended on sweeping and watering the streets by the governor of Cairo, who gave an extravagant contract for the work to a European in the town. Upon March 1st, 1886, the contract having terminated, the work was taken over by the Sanitary Department, who during the first year have been able, without reducing the staff or raising the expenditure, to buy the materials, which had hitherto only been hired by the Government. About £4000 was expended in purchasing 115 mules, 50 carts, mechanical sweepers, uniforms for *employés*, &c., and the executive work has been placed under the control of an English sergeant of the commissariat department. Comment upon this economy, which will be even more marked next year, is needless. The Government was so well pleased with the result that it invited the sanitary authorities to take charge also of the street cleansing in Alexandria, which now costs £10,000 a year. This change was effected on July 1st, but no great improvement is as yet forthcoming, because the governor there yields with manifest reluctance to the loss of power and patronage. The whole sanitary budget now amounts to £100,000.

WATER-SUPPLY OF CAIRO.

The in-take of the water company has always been from a canal coming directly from the Nile, but liable to pollution from the natives on the banks, and during last winter a deplorable state of things arose owing to the temporary stagnation of this canal, consequent on some irrigating reforms. Means have now been taken to obtain the whole water-supply from the Nile itself several yards from the bank, and this now arrives untainted at the waterworks. It is pumped out to Abbassiyeh, filtered through clean desert sand, and then distributed to such quarters of the town as are fortunate enough to be provided with a supply. Greater reforms could be introduced if the whole monopoly were not in the hands of a private company, who have within the last year succeeded in obtaining a fresh term of years from the Council of Ministers. One of the water difficulties in the town is that the pressure is not sufficient to constantly force the water higher than the first floor of the tall new houses which Europeans are now building for English tenants. This at once creates a sanitary evil of much importance.

INCREASED DEATH-RATE IN ALEXANDRIA.

During the first third of this year there were 3405 births and 2637 deaths among the native population, but during the second third of the year just ended the births fell to 2784 and the deaths rose to 3771. Since the beginning of April the deaths have invariably been in excess of the native births, and the mortality per annum has mounted from 43·5 to 62·2 per 1000. This alarming increase is said to be due to an epidemic of measles and to the bronchitis, diarrhœa, and lamentable neglect with which any such outbreak is invariably associated among Egyptians. Nearly three-fourths of the deaths are of children under five years and very many are within the first twelve months of birth.

Cairo, Sept. 4th.

THE Cirencester Hospital Sunday collections were made on the 26th ult., the result of the various appeals being highly satisfactory.

Obituary.

SAMUEL WOODMAN, M.D. DURH., F.R.C.S.

THE death of this gentleman took place at his residence in Ramsgate, at midnight, on the 15th ult., from typhoid fever. How the fatal illness was contracted is not known. It may be that he acquired it on the Continent, where he had been spending a short holiday; but it is more than possible that the germs of the disease were upon him ere he started, as before he left home he had been closely occupied with the relaying of the drains in the house into which he was then moving. It is important to note that a labourer who was employed upon the work was attacked with the same disease. Strange to say, after his return to England, Dr. Woodman, though not feeling well, was playing tennis in a country house at which he was visiting—this would be on Sept. 1st and 2nd—within a fortnight of his death. Though then bright, cheerful, and active, he had a presentiment that he was sickening for a fatal illness, and spoke to his host upon the subject. Returning to Ramsgate, he at once took to his bed (Sept 3rd) under the advice of his brother-in-law, Mr. Raven of Broadstairs, who at once recognised the serious nature of his malaise. Everything went on well at first, with the exception of the intercurrence of albuminuria; but two days before death symptoms of perforation of the bowel appeared, and with them came the fatal collapse. Though only forty-five years of age, Dr. Woodman had accomplished a larger share of work than many a man could get through in a much longer time. He was extremely active and energetic, and of a warm, impetuous temperament. He believed that language was given to express, not to conceal, one's thoughts; and thus as an opponent he was free and hard-hitting—as a friend chivalrous and endeared. By sheer force of will and power of work he had obtained the Fellowship of the College of Surgeons, and the Doctorate of Medicine of the Durham University. He was a Justice of the Peace, Presiding Councillor of the Primrose League, and chairman of the High School for Girls. Dr. Woodman was a zealous champion of straightforwardness and kindliness in professional dealings, as, indeed, in everything else, and his medical brethren would probably ascribe to his personal influence much of the good feeling which so strongly prevailed amongst them. Would it be too much to say that they regarded Woodman as their chief? The subject of this notice was about 5 ft. 9 or 10 in., strongly built, with a high forehead, cleanly cut features, and a prominent nose. No one could converse with him without observing that he was a man of unusual mental capacity, whilst his bright and cheerful manner gave assurance of excellent social parts. He recently remarked to the writer that he did not consider an obituary notice complete unless reference were made to the religious opinions of the individual. Brought up as a nonconformist, Woodman eventually joined the Church of England, whose doctrines fell more in harmony with his own liberal and intellectual opinions. More by habit than by effort, his life and acts were deeply influenced by the spirit of Christianity. He took a practical interest in everything that concerned the poor and needy, and was an active member of his parish church, in which he recently filled the office of churchwarden.

HIBBERT SULLIVAN PARKER, F.R.C.P., &c.,

SURGEON, ARMY MEDICAL STAFF.

IT is with deep regret that we have to record the death of this promising young officer, which took place at Ferozepore on August 1st last from remittent fever, at the early age of twenty-eight years, a few days only after his return to duty from three months' "privilege leave" in Kashmir.

Mr. Parker was educated at Hailebury College and at King's College, London, where he devoted a year to the Arts and Science courses. He became an A.K.C., and then proceeded to the study of medicine in King's College Hospital. He soon showed marked ability in the profession he had chosen, and gained several prizes in medicine, surgery, and gynæcology. He was for some time obstetrical house-physician to the hospital. In 1879 he became a M.R.C.S. and L.S.A., and in the following year he passed the examination for the F.R.C.S. and F.R.C.P. Edin. He entered the Medical Service of the Army in October, 1880, taking a

Digitized by Google

high place at the competitive examination, and after the usual course at Netley was gazetted to a commission on Feb. 5th, 1881. He served for about a year in England, chiefly at Woolwich, and was then ordered to India, where he arrived in March, 1882. Soon after his arrival he was posted to Ferozepore, Punjab, where he remained during the whole of his Indian service. For the last two years he had held the appointments of staff-surgeon, surgeon to the Ordnance, and had medical charge of the lock hospital at Ferozepore.

Mr. Parker was a keen lover of his profession, and regularly kept himself conversant with the medical literature of the day. He was also an extremely kind and painstaking medical officer, never giving himself a thought where his patients were concerned. He was, moreover, an ardent Freemason, and was at the time of his death Worshipful Master in Craft and Mark Lodges, Worshipful Commander of the Ark Lodge, and P.Z. of the Royal Arch Chapter at Ferozepore. He was also a Grand Steward in the District Grand Lodge of the Punjab. The deceased gentleman was under orders to return to England during the present trooping season, on the completion of his term of Indian service, and by his early death the Army Medical Service has suffered a severe and irreparable loss.

Mr. Parker was an only surviving son, and his loss will be keenly felt, not only by his immediate relatives, but by a large circle of friends both at home and in India, to whom he had endeared himself by his kindly and gentlemanly manners. He was buried in the Ferozepore cemetery on Aug. 2nd with full military honours, the funeral being attended by all the officers in garrison and by representatives from all the various Masonic lodges in Ferozepore.

Medical News.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on Thursday, the 23rd ult.:—

Evans, William Edward, St. Mary Church, Torquay.
Gedge, Arthur Johnson, Methwold, Brandon, Norfolk.
McIlroy, John Black, Derwent Villa, Shooters-hill.
Rutherford, Vickerman Henzell, Elswick-road, Newcastle-on-Tyne.
Stelfox, Harold, Rotherhithe New-road.
Woodhouse, Robert Hall, Hanover-square.

DR. GAMALEI of Odessa has been inoculating large numbers of cattle for rinderpest.

DR. VON GUDDEN'S widow has been granted the sum of £5000 from the Civil List by the Bavarian government.

PRINCE ALBERT VICTOR has accepted an invitation from the committee of the Burnley Victoria Hospital to open the new institution on the 13th inst.

THE committee of the Birmingham Hospital Sunday Fund have decided to hold the next collection on the 31st inst.

COLONIAL AND INDIAN EXHIBITION.—H.R.H. the Prince of Wales has decided that the present Exhibition shall close on the evening of Wednesday, November 10th.

DR. SCHROEDER of Vienna was lately sent for to Kieff in Russia, to perform an operation for uterine fibroid. His fee was £500.

ON the 24th ult. Mr. W. H. Browne, of Aldborough sustained a severe injury to the spine by a fall, which is likely, we regret to state, to necessitate the relinquishment of his professional duties for a considerable time.

AT the meeting of the Kilrenny School Board on the 15th ult., it was reported that the epidemic of scarlatina in Cellardyke was not of sufficient importance to warrant the closure of the elementary schools.

UNDER the title "Just one more book" the Kyrle Society has just issued an appeal for further aid for its literature branch; an appeal which deserves what it will doubtless obtain—a generous response.

ON the 28th ult. an inquest was held at North Shields on the body of a young woman who had committed suicide by drinking liquid in which the ends of lucifer matches had been steeped.

THE new Government Medical Service was inaugurated at Georgetown, British Guiana, on the 1st ult., by a largely attended and highly successful dinner, Dr. Grieve, Surgeon-General, presiding.

AN inaugural address in connexion with the Medical Prayer Union will be delivered to medical students by the Hon. and Rev. W. Talbot Rice, M.A., at 8 p.m. on the 8th inst., at St. Martins-in-the-Fields, Trafalgar-square.

UNIVERSITY OF CAMBRIDGE.—The next examination in Sanitary Science will begin on Tuesday, October 5th. The names and fees of candidates should be sent to Dr. Luard, Registrar of the University, before the end of September.

UNFITNESS FOR MILITARY SERVICE IN BAVARIA.—The Bavarian military medical authorities examined during last year 76,623 men liable to military service, and reported 49,206, or 64·2 per cent., unfit.

EXCLUSION OF FEMALE STUDENTS IN PRUSSIA.—It is stated that the Ministry of Public Instruction in Prussia has issued an order that females are not to be admitted to Prussian universities either as regular or occasional students.

THE general annual meeting of the supporters of the Royal Albert Asylum was held at Durham on the 24th ult., when satisfactory financial and medical reports were presented. An election of seventy candidates for admission was also held on the same day.

SEVERAL persons are reported to have been poisoned in a village between Canterbury and Dover, by drinking some beer, several narrow escapes from death being recorded. The cause could not be traced until the cask was examined, when, it is stated, an adder was found.

AT the weekly meeting of the Workhouse Committee of the Liverpool Select Vestry on the 23rd ult., it was reported that out of 140 cases of infectious disease in the institution during the past week, 77 were those of patients suffering from scarlatina.

A NEW high-level reservoir, which forms part of the scheme for an improved water supply and other sanitary improvements arising out of a typhoid epidemic, was formally opened at Kidderminster on Sept. 28th. The entire scheme is estimated to cost about £25,000.

HOSPITAL SATURDAY FUND.—At the usual monthly meeting of the Board of Delegates of this fund on the 25th ult., it was reported that the amount to hand from the various workshops was £1500 in excess of the amounts received to the same date last year, thus more than compensating for the falling off in the street collection.

CHURCH PARADES.—On the 26th ult., a temperance demonstration and church parade was held in aid of the funds of the Royal London Ophthalmic Hospital, Moorfields. A church parade was also held on the same day on behalf of the Evelina Hospital for Children in Southwark-bridge-road.

MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT.—The new out-patient department of this hospital is to be opened on the 8th inst. by the Earl of Derby, the patron of the institution. The extension will accommodate about 100 patients at one time, with consulting-rooms and dispensary *en suite*. To complete the building there is yet a deficiency of £1500, and the committee have issued an urgent appeal for this sum.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

DAVIES, THOMAS L., M.B., C.M.Ed., has been appointed Medical Officer for the Second District of the Conway Union.

EALES, GEORGE YOUNG, M.R.C.S., L.R.C.P., has been appointed Senior House-Surgeon to the Torbay Hospital, Torquay, vice W. G. R. Tyrrell, resigned.

FETHERSTONHAUGH, R. T., L.R.C.P.Lond., M.R.C.S., has been appointed House-Surgeon to the St. Peter's Hospital, Henrietta-street, Covent-garden, vice P. Edgelow, M.R.C.S., L.S.A., resigned.

LYON, ADAM C., M.D.Aber., has been appointed Medical Officer for the Bawtrey District of the Doncaster Union.

MCCARTHY, EDWARD C., L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Waddingham District of the Caistor Union.

Digitized by Google

MEYER, CHARLES H. L., M.B., B.S.Lond., M.R.C.S., has been appointed Medical Officer for the Sixth District of the Hollingbourn Union.

MORRIS, PRICE, L.R.C.P.Ed., L.F.P.S.Glas., has been appointed Medical Officer for the Third District of the Conway Union.

NELSON, GEORGE D., M.D.St.And., M.R.C.S., has been appointed Medical Officer for the Second District of the Bridlington Union.

SHAW, HUGH GROSVENOR, L.R.C.P., M.R.C.S., has been appointed Senior House-Surgeon to the Cancer Hospital, Brompton, vice E. W. Paul, M.R.C.S., &c., resigned.

SIMPSON, ALEXANDER, M.B., C.M.Aber., late Second Salaried Medical Officer, has been appointed House-Surgeon to the Weston-super-Mare Hospital, vice H. J. Powell, M.R.C.S., resigned.

WETWAN, W. A., M.R.C.S., L.S.A., has been appointed Medical Officer of Health for Bridlington.

Births, Marriages, and Deaths.

BIRTHS.

BARTLETT.—On the 22nd ult., at Connaught-square, the wife of Edward Bartlett, M.R.C.S., of a son.

BIGGS.—On the 19th ult., at Hillside, Child's-hill, N.W., the wife of John M. Biggs, L.R.C.P.Lond., M.R.C.S., of a daughter.

COLGATE.—On the 21st ult., at Kent Lodge, Eastbourne, the wife of Henry Colgate, M.D., F.R.C.S., of a daughter.

FOLEY.—On Aug. 13th, at Pertabghur, Assam, the wife of C. N. Foley, M.R.C.S., L.S.A., of a daughter.

FRANKS.—On the 21st ult., at Fitzwilliam-square, Dublin, the wife of Kendal Franks, M.D., of a son.

KNOBEL.—On the 5th ult., at Colesberg, Cape of Good Hope, the wife of J. B. Knobel, M.B.Glas., L.R.C.S.Ed., of a daughter.

MEREDITH.—On the 26th ult., at 6, Queen Anne-street, Cavendish-square, W., the wife of W. A. Meredith, M.B., C.M., of a daughter.

ROE.—On Aug. 29th, at Amraoti Camp, Berar, India, the wife of R. Bradley Roe, I.M.D., of a son.

SAUNDERS.—On the 3rd ult., at Mhow, Central India, the wife of Surgeon-Major W. Egerton Saunders, Medical Staff, of a son.

WALKER.—On the 24th ult., at 18, London-road, N. Lowestoft, the wife of Henry Bournes Walker, L.R.C.P., L.R.C.S.Ed., of a daughter.

MARRIAGES.

PASS—BISHOP.—On the 29th ult., at St. John the Baptist, Crowthorne, Berks, by the Rev. E. C. Wickham, Head Master of the Wellington College, assisted by the Rev. H. T. Morgan, Vicar of the Parish, Charles William Bass, M.R.C.S.E., of Langsett, Ilford, Essex, to Edith Mary, eldest daughter of George Bishop, of Wellington College, Berks.

COLDSTREAM—FRASER.—On the 23th ult., at Queen's-road Presbyterian Church, Brighton, by the Rev. Donald Fraser, D.D., of London, uncle of the bride, assisted by the Rev. A. Hamilton, D.D., of Brighton, Alexander Robert Coldstream, M.D., F.R.C.S.E., of Florence, to Janey Speirs Playfair, eldest daughter of the Rev. William Fraser, M.A., of Brighton.

COUNSELL—RITCHIE.—On the 23rd ult., at the Parish Church, Amberley, Gloucestershire, Herbert Edward Counsell, M.R.C.S., L.R.C.P., of Lyss, Hants, to Helen, youngest daughter of the late Alfred Ritchie, Esq., of Stroud.

HOOLE—ADAMS.—On the 28th ult., at St. George's, Tufnell-park, by the Rev. Marcus Rainsford, Henry Hoole, M.D.Lond., to Emily Sarah, younger daughter of the late Henry Adams, of 59, Fleet-street, E.C., and Knottywood, Priory-road, West Hampstead.

LEACH—HILL.—On the 14th ult., at St. Luke's, Torquay, Alfred Leach, L.R.C.S.Ed., L.S.A., to Edith Caroline, daughter of the late C. J. Hill, Esq., of Kenwood, near Manchester.

MACKINLAY—ALLEN.—On the 7th ult., at St. Saviour's Church, Warwick-road, W., James Grosvenor Mackinlay, F.R.C.S., to Mrs. Allen, of Blomfield-street, Westbourne-square.

PEACOCKE—VINCENT.—On the 25th ult., at St. Stephen's, East Twickenham, J. C. Harding Peacocke, Surgeon, Indian Medical Service, to Norah, daughter of the late William Vincent, of Wastdale, Terenure co., Dublin.

STEELL—MCKIE.—On the 22nd ult., at St. Paul's, Withington, Manchester, Graham Steell, M.D., to Agnes Dunlop, eldest daughter of the late Rev. Thomas McKie, of Erskine, Renfrewshire.

WILLIAMS—SMITH.—On the 21st ult., at W. Kensington, by the Rev. Dr. Sinclair Patterson, T. Hammond Williams, L.R.C.P., of Oswestry, to Annie Lucy, daughter of W. Hind Smith, Esq., of Exeter Hall, London.

DEATHS.

BELL.—On the 24th ult., at Waverley House, Hull, John Pearson Bell, M.D., J.P., late D.P.G.M., North and East Ridings of Yorkshire, in the 78th year of his age.

BERWICK.—On the 18th ult., at 7, Thornhill-crescent, Sunderland, George Berwick, M.D.

LACEY.—On the 12th ult., at Kiama, New South Wales, Chas. William Lacy, L.R.C.P.Lond., M.R.C.S.

PESKETT.—On the 21th ult., at Leyton, Essex, Alfred Peskett, M.D., aged 58.

SMIRTHWAITE.—On the 22nd ult., at his residence, Hargreaves-street, Burnley, Lancashire, Sagar Veevers Smirthwaite, M.R.C.S., L.R.C.P., aged 46.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

SANITARY REFORM.

UNDER this heading, in a letter to the *Yorkshire Post*, Mr. J. Ingham Ikin, F.R.C.S., whilst congratulating the promoters of the recent Sanitary Congress at York upon the success with which their efforts were attended, points out that in the papers which were read and the addresses which were delivered the earliest promoters and advocates of sanitary reform had scanty justice done to them. Mr. Ikin alludes chiefly to the writings, lectures, and papers of Dr. Southwood Smith, Dr. Black, Mr. Hastings, Dr. Kilgour, the late Earl of Shaftesbury, and Mr. Richardson, supported by the strong advocacy of the late Mr. Wakley, M.P., who originated a special commission to report on the subject. The Social Science Association, aided by the veteran sanitary reformers Dr. Chadwick, Dr. Lankester, and others, advanced the science of sanitary reform materially, and might, he thinks, with justice have been alluded to.

J. S.—The regulations of the General Medical Council making an examination in mechanics obligatory before qualification came into force on Jan. 1st, 1882, hence our correspondent will be obliged to pass in that subject.

Professor Clay's paper will appear in an early number.

OVERCROWDING OF THE PROFESSION.

To the Editor of THE LANCET.

SIR,—As showing the seriously overcrowded state of the profession in this country, will you permit me to state in your columns the result of an advertisement which appeared in your last issue for a "surgeon to be located on one of the West African rivers"? I received no fewer than sixty-seven replies, and they continue to arrive, six having been received by this evening's post. Very many of them are from men of very good social and professional standing, and most of them have had many years' experience in private practice. The climate of the West Coast of Africa has a notoriously evil reputation for its effects upon the European constitution; and although I believe the climate is often made the stalking-horse for the injudicious habits of many of the Europeans resident in the tropics, Africa, on its west coast, cannot be deemed the most salubrious place in the world. I have lived there myself, and can therefore vouch for the fact. The emoluments offered amounted to a guaranteed minimum of £500 a year. I answered the first score of letters; and perhaps the other gentlemen who do not receive replies will accept this letter as an acknowledgment of the trouble they have taken.

I am, Sir, yours faithfully,

Aylesbury, Sept. 28th, 1886. R. HARVEY HILLIARD, M.D.

THE BROMPTON CONSUMPTION HOSPITAL.

WE are asked to state that any former clinical assistant or pupil of the Hospital for Consumption and Diseases of the Chest, Brompton, who has not yet received an invitation to the conversazione to be held at the Hospital on Thursday evening, October 7th, will receive one on forwarding his address to Dr. Waugh, the resident medical officer.

W. F. M.—Tables of the weight of the human body and brain in health and disease may be obtained of Messrs. Churchill, New Burlington-street.

Mr. Eales (Torquay).—In an early number.

THE FIRST PROFESSIONAL EXAMINATION IN SCOTLAND.

To the Editor of THE LANCET.

SIR,—In one of the "leaders" in your Students' Number you say: "There is plenty of complaint of bad students." That may be so; but are many of these students not the victims of a badly-arranged system of teaching? I opine so. Keeping only in view the Scottish universities, it is the case that the student, after passing what is called the preliminary examinations, is confronted with chemistry, botany, and natural history: the width of which sciences, and the difficulty of successful concentration upon their study, harass and sour him near the beginning of what ought to be a delightful course of study. Mr. Paget said at one time that 10 per cent. of medical students do not complete their studies. This first professional examination has been truly a stumbling-block to some young men known to me, excellent in their character and studious in their habits, who have retired, baffled and disgusted with this examination. With others, who have appeared again and again for examination, the necessity of grinding or cramming for it has most seriously interfered with their study of anatomy, physiology, and the other practical subjects later on. Plucking is so common at this stage that it has ceased to be a disgrace to the students. I have nothing to say against individuals; but there is surely something wrong with (1) either the training of the students, (2) the relation of the examination to the previous education, or (3) the mental calibre of the students. A living professor in a Scotch university says that students are generally poor, and cannot afford to waste time and neglect their studies; and I believe him. Yet there is the humiliating fact that not a few of them pay "grinders" to post them up in the "tips" of the examiners. Philosophers may sneer at "cram"; but as the whole alpha and omega of a student's career is to get successfully through the examinations, whatever plan helps him most in that direction will have his support. If excessive stress continue to be put on chemistry, botany, and natural history, then let every practitioner who is dedicating a son to the medical profession agitate that these three subjects be included in the preliminary examination, so as not to interfere with the study of the human body and its diseases. If unable to pass this enlarged preliminary examination, the candidate could retire in reasonable time and betake himself to other pursuits.

I am, Sir, yours truly,

Sept. 24th, 1886. M.D. GLASGOW.

*** We have always urged that these scientific subjects should be passed before a student enters on his strictly medical work.—ED. L.

SAMPSON GAMGEE,

DIED SEPT. 18TH, 1886.

In Memoriam.

YEA, his the sacrificial life well spent—
Ah! who shall say that it is spent in vain?
To bind the soldier's wounds on battle-plain,
And heal the bleeding heart, by sorrow rent,
His sacred trust; and now the deathless prize
Of faith and pious works is nobly won;
And we who mourn him here shall dry our eyes
As his green grave of righteous deeds the sun
Illumes, and seraph voices chant "Well done!"

CLARENCE FOSTER.

A CASE OF GUINEA-WORM.

To the Editor of THE LANCET.

SIR,—Can any of your readers give me any advice as to the treatment of a case of guinea-worm (*Filaria medinensis*) which I have under my care? All the text-book authorities say: "Wind the worm round an ivory peg, taking care not to break him;" but they all forget to tell you what to do if the worm refuses to come out, and goes on burrowing, as it is doing in this case, and showing no signs of appearing above the surface. This guinea-worm has been in the leg about three months, and is constantly on the move. Can nothing be done, either in the way of killing it or of getting it out by an operation? If any of your readers could give me any information I should be obliged.

I am, Sir, yours truly,

Sept. 29th, 1886. READER.

CYPRUS OF THE COMMANDERY.

W. L. T. (Reading).—This wine derives its name from that part of the island of Cyprus where the "Commendatore de' Cavalieri di Malta e di Rodi" (Commander of the Knights of Malta and Rhodes) resided and exercised authority over the various insular "Commanderie" or Commanderies. The wine itself is grown in a rather primitive manner, minutely described by the Italian Consul at Larnaca, the Cavaliere E. Chicco, in the "Bolletino Consolare." It owes less to art than to nature, the vines growing well in the temperate climate of the island, where it has nothing to fear but the occasional droughts or rain-mists, while the phylloxera is unknown and the oïdium in an atmosphere so dry is almost innocuous. The grapes of the Commandery are gathered about the middle of September. The bunches, stripped or cut off the vines, are spread out on the house-tops, which are composed of mud and straw dried together, and they lie on vine-leaves exposed to the sun for some fifteen days, after which drying process they are put into heavy wine-presses. The must which is squeezed out is collected in big jars, tarred inside and closed at their narrow orifices by a cork, which is pierced with holes. There it stands till fermentation has taken place, and then the jars are hermetically sealed, and the wine remains in this condition until it is sold or consumed. Cyprus of the Commandery is hardly ever adulterated, and its growers rarely have recourse to plaster-of-Paris, because such treatment invariably leaves it turbid or with an unpleasant after-taste. The island does not grow the wood adapted for butts or barrels; so the wine is kept in jars or earthen vessels, almost entirely made by hand on the spot where they are required. These vessels are baked in the furnace, and then their interior is coated with liquefied resin. It is this resin which gives the Cypriote wines their peculiar taste, which lowers their value in European markets, and the deteriorating practice will cease only with the opening up of roads in the island which will facilitate the transport of proper materials for making casks or barrels. In its first year the wine of the Commandery is apt to acidify, owing to a second fermentation; but if this is successfully overcome, then the wine suffers no other change, not even if left for many months exposed to the air. It is then kept in wood, the casks being never disturbed. In these it matures, and becomes the rich, palatable beverage so much in favour with Italian physicians, with whom it has the credit of having prolonged for some years the life of the octogenarian, Pius IX. Since the island became English, so far as its administration is concerned, the Cypriote husbandman has gradually thrown off the lethargy contracted under the Turk. He knows he can live and thrive, the taxes being no longer fixed by despotic caprice or by dishonest speculation, but being, on the contrary, regulated by sound laws. Private enterprise is on the increase, and both the quality and the quantity of the famous Cypriote wines will be enhanced. As it is, the export, according to statistics, has so increased since 1878 that within the last two years it has doubled.

"A NEW AND IMPROVED CLAMP FOR HÆMORRHOIDS."

To the Editor of THE LANCET.

SIR,—Having seen the account of Mr. C. J. Smith's clamp in a recent number of THE LANCET, and having a suitable case on hand, I wrote to Messrs. Maw, Son, and Thompson for the instrument, and used it very satisfactorily on Sept. 16th. Just after ordering the instrument I read Mr. Fitzroy Benham's criticism in your issue of Sept. 4th; but I certainly did not find the jaws of the clamp spring in the least from the parallel direction, as he therein states—on the contrary, they held firm as a vice with each fresh application. It appears to me, and this I have suggested to the makers, that if the instrument were made curved, instead of straight, it would be much easier of application. Being straight, it can only be applied from above or below, as the patient lies on the side, and if the nates are large it is difficult to apply it closely; whereas if it were curved it would be easily applied in any direction. If Mr. Smith will allow me to make another suggestion, it is this: the jaws would be more serviceable if made a little longer, in order that more of the piles might be grasped at once, and save the necessity of too frequent applications. The screw is a little too slow; otherwise the instrument is a very useful one.—I am, Sir, yours faithfully,

Bridlington, Sept. 21st, 1886. FRANCIS C. BRETT.

SMALL-POX IN SOUTH AFRICA.

To the Editor of THE LANCET.

SIR,—I think I saw in a recent number of THE LANCET an account of the ravages of small-pox in South Africa, and of the dearth of vaccine lymph in the neighbourhood of the epidemic. I should at all times be glad to send out gratuitously to practitioners who cannot obtain it readily a supply of charged tubes, of which I have always by me many more than I want. If you would kindly publish this letter it will very probably come under the notice of practitioners in want of lymph, and they can apply to me.—I am, Sir, yours faithfully,

J. H. GRAMSHAW, M.D.,

Sept. 22nd, 1886. Public Vaccinator for Gravesend.

EDITORS AS REPRESENTATIVES.

Mr. W. D. Spanton thinks the editors of the medical journals would make the best direct representatives. We must adhere to our view that the new Council ought to be furnished, above all things, with representative general practitioners. Such men have been hitherto lightly esteemed by the medical authorities and the Medical Council. It is time that they had seats in the Council for each division of the kingdom.

Mr Wilkinson (Rotherham).—The interest of the question submitted to us rests for the most part upon local considerations. It is not easy to decide as to whether parks or baths or free libraries have superior claims on the sympathies of philanthropists. All of these provisions are important, and, if possible, should be obtained for the benefit of the community.

Dr. Thos. Reid.—To the first and third of our correspondent's questions we answer, Yes. To the second question we reply that the chemical analysis leads to the water being regarded as open to grave suspicion.

Dr. F. E. Pearse (Frome).—Will our correspondent kindly repeat his question, as his letter has been mislaid?

Dr. F. de Havilland Hall.—Will our correspondent address Dr. Saundby, of Birmingham, on the point?

Beta.—Either Carter's "Elements" or Charteris' "Practice of Medicine."

MILK-POISONING.

To the Editor of THE LANCET.

SIR,—I think public attention should be drawn to the present very injurious practice of adulterating milk during the hot weather with chemicals, which is practised at the smaller dairies. Eleven days ago my little boy, a robust child of nearly two years of age, went to bed well, but awoke at 2 P.M. in frightful agony, which continued for several hours, and with high fever. The latter soon subsided under treatment; but the child has ever since had very intractable dysentery, and has become very much pulled down. An infant was seized at the same time, but in less degree. This proved that the milk was at fault; and I have since known an exactly similar case caused by milk from the same dairy. I was unable to procure a satisfactory specimen for analysis; but it is apparently the sediment given to the child late at night, after the milk has been standing some hours, that does the mischief. I beg to subjoin a letter, with which Mr. Stokes, the Public Analyst for Paddington, has, in answer to inquiry, kindly favoured me, and remain

Your obedient servant,

Norfolk-terrace, W., Sept. 16th, 1886. HERBERT SNOW.

P.S.—I would add that the symptoms in the first instance were so acute as to suggest to me arsenical poisoning. A more delicate child might readily have succumbed.

"Analytical Laboratory, Vestry Hall, Harrow-road, W.,
"Sept. 11th, 1886.

"My dear Sir,—It is quite possible that the sediment you speak of in the milk was borax or boracic acid. Both of these are too frequently used in the milk trade during the hot weather. Being but slowly dissolved, they would, if added direct, very likely be found at the bottom of the can, even after some hours. They would act, if in any quantity, as irritants to the gastric mucous membrane. This week I received a sample of milk containing much washing soda, evidently added instead of the bicarbonate. Such samples are not obtained from the larger firms, who rely upon cold rather than upon chemicals to preserve their milk.

"Yours faithfully,

"ALF. W. STOKES, F.C.S.,
"Public Analyst to the Vestries of Paddington, Bethnal-green, and St. Luke's."

Mr. H. Craven Smith.—It is impossible to answer the question of our correspondent. The recognition of the degree in question will depend on the General Medical Council and the Privy Council. Our correspondent is right in his interpretation of the 16th clause.

Subscriber (Northampton) can hardly expect us to become the medium of the information he desires.

Practitioner has not mentioned the particular preparations he finds unsatisfactory.

Barnacle.—The paper is marked for insertion.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

Introductory Address

DELIVERED AT

ST. THOMAS'S HOSPITAL,

At the Opening of the Winter Session 1886-87,

BY J. S. BRISTOWE, M.D., LL.D., F.R.S.,
SENIOR PHYSICIAN TO THE HOSPITAL.

MR. TREASURER AND GENTLEMEN,—At the request of my colleagues I appear before you to-day to give the introductory address. I need scarcely say that I deeply appreciate the honour which they have done me, and the privilege it confers upon me of delivering myself as I please on whatever subject I may choose as suitable for the occasion; yet I must confess I would gladly have declined the honour and foregone the privilege had I dared. For, as we are constantly reminded by our critics, we orators of the 1st of October rarely say anything particularly new or particularly worth hearing; and it requires some exercise of moral courage for one who acknowledges that he has nothing new or important to say, and who finds himself for the third time in this unhappy position, to brave the adverse criticism which he feels that he shall deserve, and which has been passed upon him over and over again by anticipation. On the other hand, gentlemen, for reasons which I will briefly state, I have always been a consistent advocate of the maintenance of the custom which we are met this day to honour. It is admitted that the duties of the lectureship are difficult of adequate fulfilment; but if difficult, so much the more is success worth achieving, and at any rate the mere endeavour to do one's best is a wholesome experience (I am saying this for the benefit of my younger colleagues). The occasion is one which, as I believe, most old pupils regard with interest; and certainly it never fails to attract, besides new faces, many old friends whom it is a pleasure to greet. The introductory speechifying, moreover, however poor many of the addresses may be or may be thought to be, is made the occasion by the daily papers of drawing the attention of the public to the large hospitals and to the important educational work which is being systematically carried on in them and in the medical schools associated with them. Lastly, the oratorical display of October 1st is a time-honoured institution which links the present with the past, and on which respect for our predecessors and veneration for what is old should restrain us from laying violent hands. I felt it, therefore, my duty to accept—and I accepted readily, but not without misgiving—my present responsibility.

I have alluded to the fact that this is the third occasion on which it has fallen to me to give the introductory address. The first was eight-and-twenty years ago, and my lecture was delivered in the grand old hall of the hospital in the Borough before an audience of ladies and gentlemen (for ladies at that time were invited to be present), and prior to the distribution of prizes, which then also took place on the 1st of October. I was a young man then, and felt it a high honour to be invited by my older colleagues to represent them on the occasion; and, like a young man, I did represent them in a speech of such eloquence and floweriness that now in a calmer and more critical period of life I can scarcely understand how it was I had the presumption to deliver it or even to write it; and so full of admirable advice, that it might have been in this respect the joint production of the Archbishop of Canterbury and my friend Mr. Mac Kellar. Nevertheless, it was kindly received, and if any felt the amusement in hearing it which I felt in recently perusing it, they did not show it.

My second lecture was given four years later. In the interval vast changes had occurred. The old Borough Hospital had been sold to a Railway Company, the institution had just found a temporary home in the Surrey Zoological Gardens, and what the future was to be was a problem awaiting solution. Crude sanitary notions were at that time rampant; sanitary reformers inveighed against the iniquity of retaining establishments for the treatment of the sick in towns, and the enforced removal of St. Thomas's was hailed by them as a glorious opportunity for translating their theories into fact at the expense of one of the largest and richest metropolitan hospitals. Unfortunately, too, the treasurer for the time being, and some of the more influential governors, were largely under the influence of the prevailing sanitary craze, and also were inclined to transport the hospital wholly or in part into the country. The plan which most commended itself to them was to erect and maintain a small receiving house or hospital for acute and urgent cases in London, and to build a large hospital some miles away in the country, to which convalescent and chronic cases, and, in fact, all patients who were not likely to be injured by the journey, should be conveyed. The views of the governors had not been submitted to the medical officers for consideration, nor had their collective opinion been sought in any way; nor, again, had the medical officers (not accurately knowing what was gong on) held any meeting to discuss and consider the state of affairs. I need scarcely say that the position was a very difficult and critical one, and the prospect exceedingly gloomy. The hospital and school, both of which had been in abeyance for a few months, opened simultaneously on Oct. 1st. The inaugural ceremony, including the distribution of prizes, attended as before by ladies, took place in a large tent erected for the occasion. My address, I admit, presented occasional outbreaks of grandiloquence quite worthy of my former self, but I am pleased to say that on the whole my style had become much more sober than it was in my earlier essay; nor did I again venture after so short an interval to inflict a sermon on my younger auditors. The occasion, in fact, was unique, and I gladly availed myself of the opportunity it afforded me to discuss the future of the hospital and school, arguing as strongly as I could in favour of retaining them wholly in London, and refuting as vigorously as I dared the views (so far as I understood them) of the treasurer and his supporters. I cannot pretend that my lecture had any direct influence; but it was, I believe, the first distinct public expression of opinion adverse to the views of the sanitary crotchet-mongers, who, if they had had their way, would have ruined our school and converted our great hospital into a mere sanatorium. Subsequently, other men of greater influence and greater ability than myself took up the matter energetically from the same point of view as I had done, and before long common sense was triumphant, and the danger which had seemed imminent was averted. Few persons now know how much we are indebted to Mr. Simon and the late Mr. Whitfield for the acquisition of the magnificent site on which the hospital now stands.

My third appearance occurs under very different circumstances from those which attended my first two lectures. I was then young; I am now, I prefer not to say old, but at any rate no longer young. I was then at the bottom of the hospital staff; I am now at its summit. I then lectured to students whose younger sons are probably listening to me for the first time to-day; the troublous times have passed, and we are now, and have been for some years, in the sunshine of assured prosperity.

What should be the subject of my discourse on the present occasion? I have already uttered more good advice than I ever knew how to follow, and I do not care to furbish up my old lecture. I scolded the authorities at an important crisis in the history of the hospital, but there is no crisis now and no occasion of quarrel. Even if there were I would avoid it. You may perhaps agree with me, gentlemen, in thinking that the fact that the dates of my three addresses correspond to three important periods in the history of our hospital and school suggests, as the obvious answer to my query, that my present address should be mainly retrospective.

The first seventeen years of my professional life, during which I was successively student, teacher, and physician, were passed in connexion with the hospital in the Borough—the hospital of Meade, Fordyce, Elliotson, and Robert Williams; the hospital of Cheselden, the two Clines, Travers, and Green. It is not unnatural, therefore, that I should still feel affection and veneration for that ancient and ennobled building, and should look back wistfully to the many happy and instructive hours spent within its walls. At the time at which I became a student, the school of St. Thomas's had just emerged from that cloud of failure and disaster (the causes of which I need not enter upon) under which it had lain for many years, and though the entries were still few,

Digitized by Google

the school on the whole was extremely well managed, and the teachers as a rule were exceptionally good. The hospital, of which an excellent model is preserved in our central hall, was one of the largest and best appointed in the United Kingdom. The greater part of it dated from the early years of the last century, and bore a close resemblance to the older part of Guy's. The old wards were not perhaps exactly the kind of wards that one would erect nowadays; but they were roomy, well-ventilated, and healthy, and answered their purpose. Two new wings, abutting on the High-street, had been recently erected, and it was intended that all the ancient part of the hospital should (as funds allowed) be taken down, and replaced by blocks on the same plan. The new wings were handsome structures, and the wards the noblest I have ever seen. Had the reconstruction been completed, St. Thomas's in the Borough would have been, I think, even a grander hospital than its grand successor, though possibly its arrangements might not have so well fulfilled all the sanitary requirements of this fastidious age. The school buildings were compact and well arranged, with a magnificent lecture-theatre, and an excellent museum, library, dissecting-room, and chemical laboratory.

Among the physicians, surgeons, and other teachers were many men of high eminence. Robert Williams, the author of the classical work on "Morbid Poisons," and one of the most philosophical physicians of this or any age, was the senior physician in my first year, and died in the course of it. I only have a vague recollection of seeing him occasionally cross one or other of the hospital squares. Next to him was Dr. Burton, whose name is identified with the discovery of the blue line on the gums in connexion with plumbism. He was, as far as my memory serves me, a quiet, amiable, gentlemanly man, and much liked; but he died of cholera in the epidemic of 1849, and I never, therefore, became very well acquainted with him. Dr. Barker and Dr. (now Sir) Risdon Bennett were also members of the staff, and before long were joined by the late Dr. Peacock. It was to these three able physicians mainly that the students of the period to which I am now referring owed their training in clinical medicine. Many an old student will recall the Dr. Barker of those days, twirling a quill pen windmill-like between his finger and thumb as he walked from ward to ward. I think most of us were a little bit afraid of him; but we all acknowledged his great qualities as a physician, his intimate acquaintance with morbid anatomy, his remarkable accuracy of diagnosis, and his simplicity and directness of treatment. Very few of those who wished to learn medicine failed at one time or another to attend his clinique. Dr. Bennett, again, is not likely to be forgotten by those who studied with him at that time. He, too, was recognised as an admirable physician, and as one who gave special care to the therapeutical and dietetic treatment of disease. There was never a more painstaking, accurate, and methodical physician than Dr. Peacock. He took the notes of all his cases in great detail, and generally dictated them to his clerks. His teaching, therefore, though excellent in quality, was perhaps a trifle dry and unattractive; nevertheless, it was very highly appreciated. Among the surgeons Joseph Henry Green took the lead. He enjoyed an immense reputation, and I believe deserved it. He was of lofty stature and commanding presence, with a handsome intellectual face. He was a man of rare endowment and wide culture, and an admirable surgeon. He was a consummate orator. I did not know him at his best; for though he did his work in the hospital and school, he had ceased to take much interest in it. His lectures were the lectures which he had delivered without change for years. In the hospital visits he was always accompanied by his assistant, Mr. Solly, who did most of the duties under the eye, and liable to the correction, of his superior. John Flint South was a man of a very different stamp. He was kind-hearted, but hot-tempered and crotchety, and delighted to put on a roughness and not unfrequently a coarseness of manner which those who knew him could pardon on account of his many excellent qualities, but which to strangers and patients was often offensive. But he was a most industrious man, and performed all his duties with remarkable thoroughness and conscientiousness. I suppose people now rarely consult his great edition of Chelius's Surgery, of which his own notes formed by far the larger portion, and I am inclined to think by far the more valuable. It would be impossible in the limits of a brief address to speak of all the members of the staff. But I must not overlook Samuel Solly, Le Gros Clark and John Simon. Solly was a brilliant and enterprising surgeon. But he was more than that, for he wrote a work upon the anatomy of the brain which had and deserved a high reputation; and he was a landscape painter of no mean skill. Of Le Gros Clark and John Simon I should like to say much more than I dare. Suffice it for the moment that to these two great surgeons and to South and Solly, probably more than to any others, students were indebted for their surgical education.

Although there was abundant opportunity of learning medicine and surgery in the wards and in the out-patient rooms, students were not required, as they are at the present time, to take clinical appointments, and most of the more valuable posts that are open to them now did not then exist. The clinical clerkships were got for asking, and those who did not ask were not appointed. There was no such post as that of house-physician, but all medical duties in the absence of the physicians and surgeons were performed by the apothecary and his assistant. The dresserships were more sought for, and indeed they were of remarkable value, for the dressers enjoyed much more freedom in dealing with patients and in taking responsibility in the emergencies of practice than they are allowed at the present time. But house-surgeoncies were instituted in my own early days (I was one of the first to fill the post), and curtailment of the privileges of dressers began to take place.

We were provided with good teachers. Members of the staff were responsible for the systematic lectures on surgery and medicine, but, in addition, Dr. Marshall Hall lectured on nervous diseases, and Dr. Gregory discoursed on the exanthemata. But it was, I think, in the anatomical and physiological departments that the teaching was most systematic and best. We had no practical physiology in those days, but the systematic course of lectures was efficiently carried out. Richard Grainger had been associated with his elder brother for some years in teaching anatomy and physiology in the Webb-street School, and had been imported into St. Thomas's three years before I joined it. He was an excellent physiologist, one of the best of his day, and his lectures were singularly instructive, clear, and attractive. He was a striking illustration of the fact that a man who is in earnest may be a first-rate lecturer, in the sense of being able to make his meaning clear and to command the attention of his audience, without being in any sense an orator or even a fluent and consecutive speaker. Mr. Grainger was a tall, gentlemanly, quiet, amiable, and amiable-looking man, who took a great interest in his work, as well as in his pupils, who, in return, held him in the greatest affection. I may perhaps recall the fact that latterly much of his time was given to sanitary investigations, and that he was one of the pioneers in the field of public health. Mr. Le Gros Clark was the lecturer in anatomy; and those who know how he speaks now may judge how well and pleasantly he lectured then. Perhaps in relation to this I may venture to recall a little incident of my student days. I recollect that when I went into the anatomical theatre to hear my first lecture I had no notion until the lecturer entered the room what kind of man he was, and I have to acknowledge that I was so far attracted by the personality of the lecturer that, though I was a fairly industrious student, I proceeded to spend my time in taking his portrait in my note-book, instead of paying due attention to his discourse.

I shall not recall all the excellent men who at one time or another taught in the dissecting-room. But in my second year a gentleman became chief demonstrator who, I believe, had previously for a short time occupied the same post, and who continued chief demonstrator for more than thirty years. I speak of George Rainey, who was in the fulness of his powers, I think, during the period to which I am now specially referring. There were men at the hospital of higher intellect, of wider culture, of more imposing presence, and of greater refinement than he; but there was not one whose lessons were more highly appreciated, who had greater influence among the students, or who stands out more prominently among the memories of those days. He was a small, spare, ill-dressed, untidy man, with a bald head, auburn hair, a ruddy face, which in form, features, and expression bore a close resemblance to that of John Stewart Mill, and a weak, husky voice. He passed his time almost wholly between the dissecting-room and a small apartment with a bay window looking into the dissecting-room from above, where the chief part of his microscopical work was done. It was in this room that most of those fine injections for the microscope with which his name

Digitized by Google

is identified, and of which our museum contains a choice collection, were made; and it was here that he carried out most of those inquiries which brought him reputation as a physiologist and a thinker. Possibly some here present may call to mind one occasion when in the midst of a winter session he obtained leave of absence for six weeks. It was naturally thought he was out of health and wanted change of air. But he passed the whole of the time (excepting the nights) in his den above the dissecting-room, where he could be seen from below deeply engaged in some physiological investigations. His demonstrations were very clear and simple, and largely done by putting questions to those whom he was teaching. But the most interesting feature about the man, and that which chiefly explains the great influence he had over his pupils, was his habit, usually about luncheon time, and later in the afternoon when the daily work was drawing to a close, of sitting in front of the dissecting-room fire and entering into conversation with such pupils as happened to congregate around him. The conversations were on all kinds of topics. But, no matter how they began, they generally before long diverged into discussions concerning science, morality, or religion. A favourite method with him was to fix upon one man, to ply him with questions on the Socratic principle, and then (as often happened), having led him into contradictions, or having made him display his utter ignorance of the subject he was talking about, or having induced him to express views or sentiments which were absurd or reprehensible, to lay bare the unhappy victim's errors and inconsistencies, to overwhelm him with a torrent of chaff, sarcasm, and logic, and to wind up by expressing his own views with a manner and in language which were singularly impressive. Many a student retired from such encounters a good deal crestfallen, but few, if any, showed resentment, and many I am sure were benefited by them.

The celebrated Dr. Thomas Hodgkin had been imported from Guy's Hospital to be the demonstrator of morbid anatomy at St. Thomas's, but he remained only a short time, and had left before I entered. The growing importance of pathology, however, was fully recognised, and it was as a pathologist with clinical duties that Mr. Simon shortly afterwards was introduced into St. Thomas's Hospital. I recollect well the introductory address he delivered in the Grand Hall of the Hospital before the governors, the staff, and the students, on the occasion of his appointment, and its striking eloquence. It is needless to say that whatever Mr. Simon undertook to do, he did with all his strength, and admirably. His lectures on general pathology were always eagerly attended, and were valuable not only for what they taught directly, but for their suggestiveness, and for the impulse they gave to pathological work in the hospital. Among others who lectured at one time or another during this period were some men of assured eminence, and some who were then comparatively unknown, but have since achieved greatness. Among the former were Mr. Thomas Taylor and Dr. Dundas Thomson, distinguished chemists; among the latter, Dr. Gladstone (now a well-known member of the School Board, and a chemist of the first rank as an investigator and discoverer) and Mr. Huxley.

Any picture of the old St. Thomas's would be incomplete which did not include a sketch of the apothecary and medical secretary. There was no more striking figure in the institution than Mr. Whitfield, the third and last of his name who had filled these important posts. He was then a handsome man in the prime of life, and occupied a position which gave him immense influence. He was the apothecary, and that meant, not only that he was at the head of the drug and dispensing department, but that he was the resident medical officer, and exercised control over patients, over house-surgeons and dressers, and over nearly everybody and everything else, and that he shared with the physicians the medical fees. He was the medical secretary, and in that capacity had more authority than anyone else over the medical school and all its arrangements. He was the depository of all the unwritten rules and traditions of the hospital and school. Moreover, he was in fact, though not in name, the treasurer's prime minister. He was thus the most powerful subject in the hospital kingdom. Nor was he the man to let any advantage or influence which he possessed slip from his grasp. As a rule, he no doubt exercised his legitimate and his usurped powers for the benefit of the place, at any rate for what he thought its benefit, and took an active part in introducing useful reforms. But there is also no doubt that he was instrumental in introducing changes of which the staff did not approve, and which many of us thought and think were detrimental in their effects. He was a man of much liberality and kindness of heart, and ever a real friend to the student and all who were in need.

In some important respects the times to which I am referring were times of transition; and not only were great changes actually in progress, but the foundations were being laid of improvements which have since been effected. In my early days the nursing at St. Thomas's, like that at all other hospitals, was, to say the least, discreditable. The sisters were, for the most part, respectable women, if not trained nurses, and some were women of remarkable ability and fitness. But the nurses generally were slovenly, dirty, and disreputable, which is not to be wondered at when it is borne in mind that they not only nursed the patients, but scrubbed the floors, purchased and cooked their own food, and slept, many of them, outside the hospital. But after a few years the treasurer of that time, the late Mr. Baggallay, with the aid mainly of Mr. Whitfield and our present excellent matron, cleansed the Augean stable, and gradually introduced the system of nursing, which has become perfected with time and now prevails. The reconstruction of the nursing department led, in the course of a few years, to further far-reaching arrangements. For when, shortly after the Crimean war, Miss Nightingale had decided that the national testimonial which had been presented to her should be devoted to the establishment and maintenance of a school of nurses, she, on account of the recognised excellence of our nursing arrangements, entered into negotiations with the governors, which resulted in the establishment of the Nightingale School in connexion with St. Thomas's—a school which for more than a quarter of a century has provided skilled nurses for hospitals and infirmaries throughout the British dominions, has helped to develop and still further improve our own nursing, has been the parent of many similar institutions, and still flourishes in our midst. As I have already stated, the house-surgeoncy was instituted within my recollection. The creation of this office foretold the creation of the correlative office of house-physician. But, though the importance of such an appointment was fully recognised, it was not possible to make it until the retirement of Mr. Whitfield should leave the authorities free to deal with the clinical portion of his duties; and that was not to take place for a good many years. And lastly, the medical and surgical registrarships, appointments valuable for the hospital and valuable for those who hold them, were created towards the end of this time. It may be interesting to recall the fact that the first registrar was my colleague Dr. Ord; the second, my colleague Dr. Stone.

It will be acknowledged, I think, gentlemen, that St. Thomas's in the Borough during the time I knew it was a great and growing institution, and that the survivors of those who were then connected with it, and their heirs, are justified in looking back upon it with pride. The hospital itself was a grand hospital. As I have shown, among the physicians and surgeons were men of the greatest eminence in their profession; among the lecturers and teachers men whose teachings were unsurpassed. I am bound also to acknowledge that, though we were not always on such good terms as were desirable with the treasurer and the governors who acted with him, these gentlemen had the good of the hospital and school at heart, and did much in many ways, and much successfully, to promote their interests and advancement. The school, too, was successful. Students had excellent opportunities afforded them, and, on the whole, were well taught; and many men who have since achieved eminence were turned out by us in those days. Our numbers, too, had been gradually increasing, so that latterly we were treading on the heels of our successful rival, Guy's. When I delivered my first address in 1858 there was no suspicion of the fate that was impending; everything was prosperous, and prosperity seemed assured. A few domestic troubles occurred, indeed, about this time; but they were temporary troubles affecting the staff and teachers, and not the students, and could have had little, if any, injurious effect on the progress of the school. In 1862 the hospital became the property of a railway company, and for some months hospital and school were in abeyance.

When the crisis came it was a subject of serious consideration among those who were in authority whether the hospital should remain dormant until a new permanent hospital was erected on a new site, or whether in the meanwhile it should go into lodgings. By the adoption of the former plan much money would have been saved, which

Digitized by Google

would have gone towards defraying the cost of the new buildings; by the adoption of the latter the continuity of the beneficial functions of the hospital would be secured. I think the governors did right to adopt the latter alternative. But it was also a serious question among the members of the medical and surgical staff and the lecturers whether, even if the hospital should continue its functions, the medical school should be maintained. For some thought that the maintenance of a failing school would be attended with no credit or advantage; and everyone knew that, as in order to keep the school together the expenditure would have to go on as before, there was not only a strong probability that the surplus for division would prove scarcely worth dividing, but a possibility that the lecturers and teachers might have to put their hands into their pockets to pay for the privilege of teaching. It was decided to continue the school; and, again, I think the right course was taken. I may mention, however, that the latter anticipations were in the main justified; for on looking through my memoranda for the purposes of this address, I find that for seven years of those passed in our temporary abode my average yearly income from the school was just £16 10*s*., and in one year amounted to the magnificent total of £12. I was lecturing on physiology with Dr. Ord.

The site acquired for the temporary hospital and school was the old Surrey Zoological gardens, which had ceased for some few years to fulfil their original functions, and in which there had subsequently been erected a large hall for music and dancing, where also Thackeray lectured and Spurgeon preached. With no little skill the building was converted into a hospital of three floors, of which the lowest one was devoted, half to the purposes of a ward, half to the out-patient department, and of which each of the upper two floors constituted one magnificent ward holding upwards of eighty patients. The hospital contained about half the number of beds the old hospital had contained. It was designed only for temporary occupation, and its plans and arrangements had of course to be made conformably to the capabilities of the building to be adapted. Nevertheless, the arrangements were really good; the wards were very imposing, light, airy, and convenient, and they remained sweet and healthy to the last. The infectious cases were accommodated in the giraffe-house. The museum, library, dissecting room, and lecture theatres were distributed about the grounds, some occupying the monkey-house and other former abodes of beasts or birds. The school buildings, though they had been hastily prepared and were somewhat rough in character, were fairly convenient, and no one had much reason to complain of them. But the charm of the place was the beautiful and large garden in the midst of which the hospital and school were placed, with its pretty walks, its avenues and copses, its flower beds and lawns, and its picturesque lake of one or two acres or more in extent.

By this time many changes had taken place in our staff of medical officers and lecturers, and many others occurred before we found ourselves in the building in which we are now assembled. Green and South had retired from the surgical staff, and Grainger from the physiological lectureship, and, among others, Dr. Brinton had been added to our number. Before we left the Surrey Gardens Barker and Bennett, Solly and Le Gros Clark, had all taken farewell of us, and Brinton had died. I may add that few of the later vacancies thus created were immediately filled up; not, however, because suitable applicants were not forthcoming, but partly because a large staff was not needed for the work of the hospital, and partly because it was thought best that the inauguration of the new hospital that was preparing for us should be made the occasion for strengthening the staff by the addition to it of a careful selection of men of eminence or of promise, whether educated in our school or attracted from other institutions.

There are two men whose names are identified with the later history of the old hospital and the earlier history of the temporary hospital of whom I may venture to speak. Dr. Brinton became connected with the school, as Mr. Grainger's coadjutor in the chair of physiology, at a time when Mr. Grainger was beginning to find his strength failing and unequal to the work required of him. He was a man of much ability and brilliancy, an eloquent and effective lecturer, and, as a physiological lecturer should be, an excellent draughtsman. After a few years he was appointed one of the physicians, and at once took a leading position as a clinical teacher. His career unfortunately was a short one, and he died while quite young of kidney disease. The other was a man whom I have not yet named, and who, I daresay, has long slipped out of the memory of many here who were once familiar with him. I speak of Edmund Montgomery, who for several years was our demonstrator of morbid anatomy. I think, however, some may manage to recall that tall, slim, handsome young man, with his profusion of crisp, curly, dark hair; with his British name but German accent, for he had been brought up from infancy in Germany among Germans, and when he came to England a few years before he joined us knew little or nothing of the English language. Some of us who were intimate with him knew that he possessed a depth and striking originality of thought, an extent of knowledge, and a command of language which casual acquaintance would probably never have suspected of him. It must be more than twenty years since he left us, and nearly as many since circumstances took him to the wilds of Texas, where he has since resided, leading (not from choice) the precarious and hard existence of a backwoodsman. It will surprise most, and I hope gratify many, of those who were his friends to learn that among his rough, uncouth, and uncongenial surroundings, in spite of continuous daily toil and penury, he has continued to pursue his philosophical studies, and that his papers published during the last few years, discussing with exquisite eloquence profound metaphysical problems, have secured for him at length a foremost place amongst American, and I believe European, philosophers.

Although our migration to the Surrey Gardens, and our sojourn there, were in many ways of serious injury to most of us, although our labours there were carried on under many discouragements and with much inconvenience, although for the second time within the memory of some among us the school had become unprosperous, and although we looked forward to the better days which we saw approaching, I must acknowledge that I look back to our nine years' sojourn in the Surrey Gardens with much more pleasure than pain. There was much good fellowship between all those who were banded together to carry on the work of the institution. The few pupils we had were of more than average merit; they were, I think, content, and certainly were loyal. And there are few more pleasing recollections than those of the academic shades haunted by the studious and meditative, of the grassy lawns alive with cricketers and others who indulged in athletic exercises, and of the frozen lake gay with its crowds of skaters.

The scene once more changes. In 1871 Her Majesty opened the magnificent hospital within the walls of which we are now assembled—a hospital, as far as I know, unsurpassed, and which, whatever its faults may be, and despite all the adverse criticisms of native faultfinders, is the admiration of almost every foreigner that visits it. We turned our backs on the old Surrey Gardens, over which the tide of time has since swept, carrying away with it everything of interest and beauty that adorned its surface, and leaving only a sediment of bricks and mortar; and we entered on our new career with the commencement of the winter session. The hospital, which was now practically completed, had been three years building. During this time arrangements (in which the medical officers had had no unimportant share) were carefully made for strengthening, by the infusion of new blood, the staff, which had been undergoing attenuation through the successive retirement of some of its most experienced and ablest members, and for effecting many improvements in the hospital and school. Among those who were invited to become members of the staff were, on the surgical side, Mr. (now Sir William) Mac Cormac (who indeed joined us ere we left the Surrey Gardens), recommended to us by his brilliant services during the Franco-Prussian war, and by his recently-published "Notes and Recollections of an Ambulance Surgeon"; Mr. Francis Mason, one of Sir William Fergusson's favourite pupils; and Mr. Henry Arnott, who has since left us for the Church, but whom we selected on account of his scientific promise;—on the medical side, Dr. Murchison, whose reputation was even then world-wide; Dr. John Harley, who had passed a distinguished career at King's College; and Dr. Payne, who had already made a reputation for himself as a pathologist;—and, lastly, in the ophthalmic department, Richard Liebreich, at once oculist, artist, and musician. It will probably still be allowed, as I think was acknowledged at the time, that the selection was, on the whole, well made, and that the addition of these to a still larger

Digitized by Google

number of able and distinguished men, already fellow-workers for years, constituted a strong and many-sided staff. Among the beneficial reforms introduced into the hospital were those relating to the resident medical appointments. The long-delayed retirement of the apothecary, who, however, retained his medical secretaryship, made it possible to put the drug and dispensary departments under the care of an educated pharmaceutical chemist, and to bring the arrangements for the care of the medical patients, during the absence of the physicians, into harmony with the corresponding surgical arrangements. I will not discuss details; but all who know anything about the hospital, are aware that the plan of having a resident assistant-physician and a resident assistant-surgeon, who enjoy supreme control in the absence of their superiors over the medical and surgical patients respectively, house-physicians and house-surgeons, who are responsible under these rules for the specific care of groups of patients, and clinical clerks and dressers at the bottom of the scale, who perform various subordinate but necessary duties in respect of the patients and make records of their cases, has answered admirably in practice; that the scientific interests of the medical officers, the educational interests of the pupils, and the sanatory interests of the patients alike have been more and more advanced; and that, while no doubt the nursing of the hospital has been undergoing gradual improvement under the direct and indirect influence of the Nightingale School, the relations between the nursing department on the one hand, and the medical students and others who work in the wards on the other, has become more and more friendly and pleasant. Indeed, the experience at St. Thomas's has shown in the most striking manner that a large medical school and a large nursing school may be carried on concurrently in the same institution, not only without jealously and without quarrels, but with the maintenance of the most cordial relations and to their mutual benefit. Among the clinical improvements, it must not be overlooked that the obstetrical has advanced like other departments, and that the specialties, more particularly perhaps those relating to the eye and throat, have been developed with singular success.

As regards the school, old lectureships and demonstratorships were rearranged, and new lectureships and demonstratorships were created; a redistribution of appointments was effected, and the newly added members of the staff had freely allotted to them such posts as seemed best suited to their abilities and their lines of work. It would be impossible within the limits of time at my disposal to discuss all the changes that were made. Moreover, many further changes have occurred between that time and the present. I may, however, refer to two or three matters. A few years ago practical physiology as a course for medical students was undreamed of; but a department of practical physiology was provided for in the new school, and has been, and is being, conducted with much success. It is only within the last few years that the pathological importance of microbes has been discovered and bacteriology has come to be recognised as an important part of medical study. Thanks to the energy and scientific spirit of Mr. Ballance and Dr. Theodore Acland, a bacteriological laboratory has been established, and is in work. It is well known that the museum of St. Thomas's Hospital has always been peculiarly rich in pathological specimens, and that it contains a series of preparations which are of great historical interest, notably Sir Astley Cooper's collection, including many of those from which the illustrations for his works were taken. The museum was much damaged by its two removals and during its sojourn in the Surrey Gardens; but since it has again found a suitable home, its importance and value have increased year by year, and now, in its way, I should think it is almost unrivalled. We are indebted for the progress, largely to the enlightened liberality of the treasurer and governors, but directly to the admirable labours of two successive curators: Professor Charles Stewart, who was with us for many years, and who was a year or two ago, much to our loss, elevated to the curatorship of the museum of the College of Surgeons; and Samuel Shattock, who now occupies the post, and has signalised his brief tenure of office by the most splendid work, and of whom I may mention especially that during the last few months, with the aid of Dr. Stone and Mr. Plowman, he has rearranged, renovated, and enlarged the Museum of Materia Medica, which, now that it is completed, is probably the finest, most perfect, and most serviceable museum of the kind in existence.

Year by year, gentlemen, during the fifteen years we have occupied our present site, our school, which had been so often and so seriously checked in its career, has increased in usefulness and prosperity, until once more it occupies a leading position among the metropolitan schools of medicine. Nor can I see any cloud in the horizon—any reason why our success should not be maintained in the future. But while the school grows and prospers those who contribute to its progress drop out one by one, and one by one new comers fill the places thus vacated. Fifteen years is a short time—at any rate seems short to those whose journey of life approaches completion, and for whom the abyss into which all must finally plunge is already within easy distance. Yet many changes have occurred even in this short time; and not only have we had losses amongst those who were with us from the beginning, but some of those who joined us later have disappeared from our midst. Some have died; some have left us from age or from ill health; some have transferred themselves to other spheres of usefulness. Our late treasurer, Sir Francis Hicks, under whose reign the present hospital was built, and to whose sagacious energy we are indebted for the carrying out of most of the improvements which I have discussed, died after a short illness nine years ago. Mr. Whitfield passed away a year earlier. Poor old Rainey, whose laborious and useful career among us had extended over so many years, worked with us for a time at this hospital; but he was falling into ill health, and probably few of those who only knew him here could form any conception of what kind of man he had been. He retired on a pension some years ago, and died but recently. Peacock and Murchison are both dead; and it is only within the last few months that poor Frank Mason, whose genial temper and kindness of heart had won for him the warm affection of all his colleagues and of everyone who knew him, whose musical accomplishments were our admiration and delight, and whose eminence as a surgeon was universally recognised, was, to our infinite loss and grief, snatched away by death, in the prime of life, in the fulness of his powers, and when there seemed for him the promise and the assurance of a long and prosperous career. But great though our sorrow is when those we love are removed from among us, Time, the healer, brings its compensation in the hallowed memories that remain when the sting of loss is no longer acutely felt. And irreparable though our loss may seem when eminent colleagues and great teachers depart, they are yet not wholly lost to us, for their names, their examples, and their works survive and add accumulating lustre to the school which they adorned.

I have now completed, however inadequately, the task which I had set before myself; and it only remains for me to give, on behalf of myself and colleagues, a cordial welcome to you who come among us to-day for the first time; to advise you to do your duty, and work systematically at your studies, for you have much to do and little time to do it in; and to urge you here and in the future to show yourselves worthy heirs of those proud traditions which are the common heritage of all who join our ancient hospital and ancient school; and lastly, to thank you, Mr. Treasurer, and you my audience, for the kind patience with which you have listened to my address.

ON BASIC TUBERCULOUS PHTHISIS.

By PERCY KIDD, M.D., F.R.C.P.,
ASSISTANT-PHYSICIAN AND PATHOLOGIST AT THE BROMPTON HOSPITAL.

(*Concluded from p. 617.*)

Cases where the Physical Signs were at first confined to the Base. Post-mortem: Oldest Disease at the Apex.

1. G. W——, aged twenty-one, engineer, admitted in August, 1883. Family history of phthisis very marked. Winter cough for three years. Continued cough and symptoms of phthisis for two months. At right posterior base, dulness, bronchial breathing, and scanty subcrepitant râles; at left base a few similar râles. Gradual extension of disease, and death from pneumothorax one month later.

Necropsy.—Lobular caseous infiltration of right upper lobe, with a small cavity at the apex, which had perforated the pleura. Lower parts of lung showed a massive catarrhal pneumonia of a greyish pink colour, marked with small yellowish spots. Left lung showed scattered nodular

Digitized by Google

disease only. The disease was evidently oldest in the right upper lobe.

2. E. B——, aged thirty-four, female, admitted in July, 1883. Winter cough for two years. Slight hæmoptysis in the summer of 1882. Cough worse since her confinement in March, 1883, and several attacks of hæmoptysis. At right posterior base dulness and crepitation; in the left interscapular region some crepitation also. The diagnosis at first was "chronic pneumonia," but was soon altered to "phthisis." The patient died in November, 1883.

Necropsy.—The right lung contained a large apex trabeculated cavity with several small cavities in upper lobe. The lower parts were studded with tuberculous nodules, but contained no cavities. The left lung showed similar but less advanced disease, with one small cavity at the apex only.

3. H. N——, aged thirty-seven, female, admitted in September, 1883. She had pleurisy thirteen years ago; cough and expectoration for nine months. At the right posterior base there was slight dulness and subcrepitant râles. Gradual extension of disease, and death from pneumothorax in March, 1884.

Necropsy.—Right upper lobe entirely excavated. A large cavity at the apex of the lower lobe. The rest of the middle and lower lobes was studded with caseating nodules, and contained a few small cavities. The left apex contained one small cavity, and was very fibroid and studded with some old dry caseous nodules; the rest of the lung was spongy, and contained a few tuberculous nodules. There was one small cavity in the lower part of the upper lobe. The oldest disease here seemed to be situated in the right upper lobe.

Cases where the Physical Signs were most marked at first at the Base, but were present also at the Apex. Post-mortem: Oldest Disease at the Apex.

1. T. M——, male, aged fifty-two, admitted in October, 1884. His mother died of phthisis. The patient had been ailing for three months, and had had cough, expectoration, &c. At the left posterior base, dulness, bronchial breathing, and subcrepitant râles; a few similar râles at the left apex also. The disease extended gradually, and the patient sank.

Necropsy.—Pleura over left lung much thickened along the posterior border; left upper lobe fibroid posteriorly, and studded with caseous nodules; at the apex a large trabeculated cavity; anterior parts spongy, but contained some tuberculous nodules; lower lobe fibroid at its apex, and contained a small cavity; remainder of lobe spongy and studded with a few nodules. Right lung emphysematous; it contained a few scattered nodules, most abundant at the upper parts. Disease most advanced and oldest at the apex of left upper lobe. Old disease also at apex of lower lobe.

2. E. M——, female, aged forty-three, admitted in February, 1886. Had suffered from occasional winter cough for some time; for the last nine months continued cough and expectoration. Physical examination revealed contraction of the left side; dulness throughout, most marked at posterior base; breath sounds weak over front and at posterior aspect of apex, with increased vocal resonance. Behind, at the base and lower interscapular region, there were intense cavernous signs, amphoric breathing, and gurgling râles. On the right side the breath sounds were exaggerated. The case was thought to be possibly an empyema communicating with the lung, or fibroid disease of the base and bronchiectasis. The patient died suddenly from profuse hæmoptysis.

Necropsy.—The apex of the left lung contained a very old cavity, with dense, blackish, fibroid walls, and the pleura in this region was very much thickened. The bronchus leading to the cavity was greatly constricted by the fibroid growth. The lower lobe contained numerous cavities of more recent date, and the lung was studded with numerous nodular caseous masses. A ruptured pulmonary aneurysm was found in one of the cavities in the lower lobe. The right lung was spongy, but contained some tuberculous nodules.

A consideration of the foregoing cases will show, I think, how easily an erroneous estimate of the proportion of basic to apical phthisis might have been framed if the clinical investigation had not been supplemented by post-mortem examination. To Cases 1 and 2, which I described first, six or seven others might have been added in which the clinical evidence of basic phthisis was fairly strong, and the number of basic cases then would have appeared to be at least eight in a total of 412, or about one in fifty. The fact that physical signs of disease are at first limited to the base, or are more marked here, does not prove that the disease has originated in this position, and does not preclude the existence of older lesions in the upper parts of the lung. In making post-mortem examinations of cases of phthisis it is not uncommon to find that one lung is apparently healthy, whereas, on making the usual sections of the organ, deeply seated nodules or even cavities are discovered, surrounded by healthy lung. Such lesions are usually not recognised, and often cannot be detected during life. The existence of cavities of considerable size in the apex of the lung may be masked by other conditions—e.g., great thickening of the pleura, rigidity of the walls of the vomica, or, what is still more important, narrowing or obliteration of the bronchus leading to the cavity. It must be remembered that cavities and other diseased conditions of the apex are much more likely to escape detection than similar lesions of the base. At the lower part of the lung the respiratory current is extremely vigorous, owing to the proximity of the diaphragm and the greater range of expansion possessed by the chest walls in this region. On the other hand, the circulation of air in the apex is much less forcible, as the result of its greater distance from the diaphragm and the comparatively unyielding nature of the upper part of the thorax. If, in addition to these natural disadvantages, the elasticity of the apex is impaired, there must be a corresponding weakening of the respiratory current in this part of the lung. When excessive secretion accompanies such a transformation of the apex, as is so commonly the case, we have the effects of obstruction of the bronchus superadded to the diminished expansion of the lung tissue, and there may be no auscultatory signs to help us beyond weakness or absence of the respiratory murmur. This condition is more likely to be produced where there is a permanent obstruction of the bronchus in question from surrounding fibrous contraction or from other causes, which need not be discussed here.

It remains now to account for the presence of marked physical signs at the base in those cases where old apex disease gives no evidence of its existence. The physical signs are probably the result of a congestive or inflammatory condition associated with œdema, and at times with partial collapse, of the lung. The lower lobes are known to be specially prone to such affections, and the lungs of persons that are already the subjects of tuberculosis are more liable to intercurrent congestions than healthy lungs. The presence of scattered tuberculous nodules might of course give rise to a localised congestion, but I do not think it is necessary to assume the existence of actual tuberculous lesions at the base in all such cases. This view receives some support from the analogy of pleuritic effusion in phthisical patients. Clinical and post-mortem experience would seem to show that such pleurisies are by no means invariably tuberculous. It is difficult to see why the disease departed from its usual order, and selected the base as its starting-point in Cases 1 and 2. As far as could be ascertained, there had been no previous affection of the lung that could have impaired the vitality of the base in either case, though such an explanation is naturally suggested at first. In both instances the patients stated that they caught cold some few months previously, and never recovered from the effects of it. It may be that the initial affection was a simple congestion or pneumonic attack of the base, which prepared the soil in this region for tuberculous infection. I cannot believe, however, that this is the whole explanation; for on this supposition basic phthisis should be of more frequent occurrence than it actually is. It would be admitted, I think, that a history such as this is not uncommonly given by phthisical patients, in whom it is the rule to find the disease limited to the apex at the outset. It is worthy of note that both the cases described were men. Dr. Pollock (*loc. cit.*) mentions that of the sixty-four cases in which he found the base most affected fifty were males.

The special incidence of phthisis on the apex of the lung has yet to be adequately accounted for. It is unnecessary here to enumerate the various explanations that have been suggested, none of which are entirely satisfactory. There is certainly much evidence in favour of the view that phthisis, in most cases at least, is the result of the entrance of a virus into the lung through the respiratory passages, though it is probably an indispensable condition that the lung shall be in some way prepared for the reception of the

Digitized by Google

poison. If this be so, it is not unlikely that the phthisical proclivity of special regions of the lung will be found to depend, in part at least, on certain peculiarities of the corresponding bronchial tract. In his monograph on "Pulmonary Hæmorrhage," Dr. Reginald Thompson makes a remark which I think suggests one factor in the case. In speaking of the respiration of the upper lobe, he says (p. 23), "The bronchial tubes of this lobe, which are not altered in size, remain permanently open, and do not filter the air in the same way as the bronchial tubes of the lower lung." If we compare the slight expansion of the upper lobe which takes place in ordinary respiration with the free expansion and contraction of the lower lobes depending on the immediate action of the diaphragm, assisted by the elasticity of the lower thoracic walls, we must acknowledge the truth of Dr. Thompson's statement. The bearing of this fact on the direction most likely to be taken by particles inhaled into the air passages is obvious.

In conclusion, it may be said that the cases which have been related show that the diagnosis of basic phthisis is not so easy as would appear to be the case at first sight. There are several diseases of the base which cannot always be distinguished from tuberculosis by the ordinary methods of examination. Without attempting to discuss the diagnosis of these various diseases, I would strongly urge the importance of a routine examination of the sputum in all such cases. I could quote instances where a most unexpected light was thrown on the case by this means. True basic tuberculosis is extremely rare; I believe it is even rarer than it is commonly thought to be; whereas the base is specially prone to other affections. I would suggest that the question which has been discussed not only possesses pathological interest, but has also a distinct bearing on the prognosis of certain cases. Keeping in mind the extreme rarity of primary basic tuberculosis, we may reasonably hope that a given case of localised disease of the base is not tuberculous, and if we fail to discover tubercle bacilli in the sputum on repeated examination, our hope becomes almost a certainty. But inasmuch as non-tuberculous disease of the base may be complicated by the supervention of tuberculosis, as in four of the cases that have been described, it is well to examine the sputum at intervals, even when we are satisfied in the first instance as to the non-tuberculous nature of the case, especially if the patient's progress be unsatisfactory. It may be said that the prognosis of chronic disease of the base is generally unfavourable, and this is true up to a certain point; but if tuberculosis can be excluded, a more hopeful prognosis may generally be given.

Brook street, W.

SOME REMARKS ON THE OPERATIVE TREATMENT OF CHRONIC OBSTRUCTION OF THE SMALL INTESTINE.

BY R. L. KNAGGS, M.A., B.C. CANTAB., F.R.C.S. ENG.

THOUGH intestinal obstruction has been brought prominently forward of late years at the Societies and in the journals, the operative treatment of chronic obstruction, when the small intestine is the seat of the disease, has attracted but very little notice. This may result from a feeling that was expressed in 1863 by Dr. Fagge, that "contractions[1] are *par excellence* the cases in which an operation must necessarily fail." But a study of Dr. Fagge's own cases—sixteen in number, three of which were hopeless cases of malignant disease—shows that there were no less than nine in which modern surgery might have interfered, otherwise than by a palliative enterotomy, with some prospects of success. It is true post-mortem records may appear to lend themselves to surgical ideas with much greater ease than the cases themselves would have done, but, after making some allowance for this, there would still remain a considerable proportion not beyond the surgeon's aid. This fact alone is sufficient to justify exploratory laparotomy in all cases of obstruction from contractions which are not obviously hopeless.

But though exploration is not unfrequently undertaken, it seems generally to end in an attempt to obtain relief by enterotomy only, or further action is altogether abandoned. Now, though this operation in the majority of cases can only be expected to be palliative, it occasionally proves to be of greater value, as will be seen from cases quoted further on. Its *modus operandi* is probably to relieve the distension above the obstruction—a condition which in not a few is sufficient to cause complete occlusion of the intestinal canal; and when by this relief the channel is once more opened, the intestinal contents are enabled to pursue the normal course, care in diet and medication being quite sufficient to prevent a fresh accumulation taking place. But these cases can hardly be considered to be free from the danger of a fresh obstruction occurring at future dates; though, should that happen, the reopening of the old wound would probably be all that was needed for their relief.

So few cases of operation bearing upon this form of obstruction have been recorded during the last seven years that the following are all that have been obtained from the different available sources.

1. Mr. Sidney Jones[2] records a case of chronic obstruction resulting from localised peritonitis, consequent upon ovariotomy performed four years previously. Enterotomy was performed after abdominal section, the artificial anus being 29 in. from the ileo-cæcal valve and the intervening coils, and the cæcum "being matted together by glandular and inflammatory infiltration." The patient survived three weeks.

2 and 3. Dr. Malins[3] records two cases in which obstruction occurred from adhesions of the intestines from pelvic inflammation. In one laparo-enterotomy was performed with success, and the artificial opening closed spontaneously, the natural passage becoming restored. In the other the same operation was adopted, but first some adhesions were separated. When reported, the bowels acted weekly, and the artificial anus, though diminishing, had not closed.

4. Mr. Treves[4] records the case of a woman upon whom he operated for obstruction three months after the reduction of an inflamed hernia. Laparotomy was performed, and a distended coil was found adherent in a bent position close to the femoral ring. The adhesions were broken down, and the case did well.

5. Mr. Meredith,[5] at the Clinical Society, recorded the case of a woman in whom intestinal obstruction set in a week after ovariotomy, which had been complicated with general adhesions. Laparotomy was performed early, and two separate coils of intestine were found kinked and obstructed by the traction of two separate omental bands. These were released, and the patient was in good health six months after.

In these few cases enterotomy has certainly played a successful part, but such success is exceptional and cannot be held to justify the employment of enterotomy in the hope of its being a curative procedure. The attempt to remove the obstruction by the separation of adhesions alone was made in two cases, but one, being an example of acute obstruction, perhaps hardly comes within the scope of this paper. No record of resection of the intestine for this condition, except Koeberlé's case (*vide infra*) has been found, and yet it is particularly applicable, as Mr. Treves has pointed out, for those cases where the obstruction is due to the effects of a contracted mesentery.

In Dr. Fagge's forty-ninth case[6] the cause of the obstruction "was found in a mass of rounded tubercles in size from that of a pigeon's egg to a nut. These formed collectively a mass as large as a small fist, situated in the mesentery close upon the intestines, and the surrounding inflammation, which appeared to have been long passed, had by contraction produced much puckering, shortening, and thickening of the mesentery, and so complete a stricture of the intestine that scarce room was left for the passage of a small quill." Here is a case in which resection seems to be specially indicated; whilst in the preceding one (Dr. Fagge's forty-eighth case), though several feet of bowel were implicated in the obstruction, which was also due to disease of the mesenteric glands, the same operation might also have been found possible; and in considering the propriety of resection in any particular case, it may be remembered that as much as two yards of small intestine have been successfully removed by Koeberlé.[7]

Cases may occasionally present themselves in which relief

[1] The term "contractions" includes several pathological conditions—such as matting of intestine, kinking by traction of adhesions &c., adhesions compressing the gut, and shrinking of the mesentery. Though "contractions" practically comprise all cases of chronic obstruction of the small intestine, three of Dr. Fagge's cases affected the large intestine.

Digitized by Google

may be afforded by some exceptional method, which the condition of the parts will suggest. Such would Dr. Fagge's fiftieth case seem to have been. In this, "three feet from the cæcum a portion of small intestine, not more than an inch in length, was pale, empty, and contracted. Opposite the constricted point the mesentery contained a group of enlarged strumous glands, the largest the size of a walnut, filled with chalky matter. It appeared as if these glands, more particularly the largest, had by their growth and increase drawn a portion of mesentery backwards to the spine, and thus, by expanding the two layers of the serous membrane and widening the base of the peritoneal ligament, had acted like a broad ligature." Here, though somewhat contracted, the channel was not completely obstructed, and it is possible that the less serious operation of enucleation of glands might have removed both the obstruction and the disease. Now, although a fair proportion of cases of "contraction" might be satisfactorily treated either by enterotomy, which might lead to cure, or by division of adhesions, or by resection, or possibly by some other method which particular conditions might suggest; yet there will be met with cases in which the second and third plans can hardly be entertained because of the large amount of bowel implicated, or the intimate nature of the adhesions between the matted bowel and other parts, or perhaps for other reasons.

In the *British Medical Journal* of Feb. 13th and March 13th, 1886, cases of pyloric stricture are recorded by Mr. A. E. Barker and by Mr. T. H. Morse of Norwich, in which it was attempted, in one case with success, to open a fresh path for the passage of alimentary matters by uniting an opening in the jejunum with an opening in the stomach. This idea, apparently new to English practice, is capable of a much wider application, and it is probable that it may be found of use in dealing with certain cases of contractions not amenable to the two methods just alluded to, and yet in which enterotomy, with its attendant discomforts and probable evils, should be avoided if possible. It must be remembered that in the latter operation, in these cases, the small intestine may be opened, either of necessity or by accident, high up; and that if the fæcal fistula does not close, the whole or a part of the contents of the intestine are discharged from the body in a very imperfectly digested state.

Quite apart, then, from other discomforts which are likely to be present, the results of malnutrition will not be long delayed, and the patient may die of inanition as the result of an operation undertaken in the hope of saving his life. If, however, a connexion can be made between the intestine above and the intestine below the obstructing coil or coils, a fæcal fistula is avoided, and the absorbing power of the intestine below the obstruction is still utilised. Moreover, in some cases the coils constituting the obstruction may be rendered useful; for the distension above them, being relieved entirely at the operation, would be prevented from again taking place, and the passage through the obstruction might possibly be reopened and kept patent. The intestinal contents, having a choice of two ways, would probably make use of both, and in the event of any renewal of obstruction occurring, or should the original track remain impervious, the artificial deviation would become the regular channel. It might act either as a safety valve, as a colotomy wound has been known to do, or it might replace entirely the normal canal. By this operation extensive division of adhesions between coils, and between coils and the parietes, might be avoided, and less risk would be run of fresh adhesions forming and a similar state of affairs resulting. The obstruction would be overcome without interfering with its cause—a point of considerable importance, and one which hitherto has only been accomplished by enterotomy, to which there are grave objections. Lastly, it is interesting to note that Nature has herself solved the difficulty in this very way, though in Nature's cure there existed imperfections that art might hope to avoid. The case referred to is the well-known one recorded by Mr. Birkett.[8] In this case a loop of small intestine contained in a strangulated inguinal hernia, which had been reduced, was found to have become adherent, and narrowly constricted at the site of the neck of the sac. A communication had formed between the adherent coils above the constriction, and this communication had served as the channel for the passage of the contents of the small intestine. Death was caused by extravasation of fæces through the breaking down of some of the adhesions.

(To be concluded.)

TROPICAL ABSCESS OF THE LIVER.[1]

By SURGEON A. TOMES,
INDIAN MEDICAL SERVICE.

THE term "tropical" applies to those large, usually single, but frequently multiple abscesses of the liver which are met with in persons who reside in the tropics, or who have been subjected to tropical influence at some period of their lives, and which are the result of a parenchymatous inflammation of the organ induced mainly by such influence. The disease is now so well known and recognised as an independent affection that further definition is unnecessary. On the average, hepatitis causes every year 1600 admissions to hospital, from 70 to 80 deaths, and from 160 to 200 invalidings, in the British army in India, consisting of 56,000 men. This heading includes many cases of "liver" that do not go on to suppuration, but the deaths are to be attributed to abscess.

In the Bengal army, with a strength of from 35,000 to 38,000, the average annual admissions for the five-year period 1877-81, for liver-abscess alone, amounted to 63. Broadly speaking, the admission-rate for hepatitis in the army in India is over 28·9 per 1000 of strength, the invaliding rate 3·03, and the death-rate 1·13, the admission-rate for abscess in Bengal being 1·8 per 1000. All parts of the peninsula are not equally unhealthy in respect of hepatitis. The Madras Presidency comes first and Bengal follows. In 1883 the mortality was distributed thus:—Madras army, 1·72 per 1000; Bengal army, 1·06; Bombay army, 0·82.

It is open to doubt whether army returns fairly represent the liability of Europeans generally, irrespective of class or occupation. The proportion of admissions to hospital for hepatitis to total admissions is 2·1 per cent. in the army. What it is in civil life I have not been able to ascertain. Nor have we the means of determining the liability according to class. My own impression is that no great difference obtains, if any, in respect of class or occupation. Cases of abscess are constantly being reported from civil practice, and for every one so recorded there must be many that we hear nothing of, while every case is recorded in the army.

The next question is, to what extent is the native of the country liable? It was formerly supposed that he enjoyed almost complete immunity. Everyone who has had experience in native practice must be aware that this is not the case. That hepatitis is far less common in the natives than in foreigners is strikingly shown by the accompanying figures for 1883.

	Admissions per 1000.	Deaths per 1000.
British army (54,673)	1602 = 28·9	63 = 1·13
Native army (114,830)	173 = 1·5	21 = 0·18
Native gaols (88,174)	87 = 1·0	19 = 0·22

While in British military hospitals the proportion of admissions for hepatitis to total is 2·1 per cent., in native military hospitals it is only ·16 per cent., and in native gaols ·09 per cent.

My experience leads me to believe that the disease is not necessarily so rare among natives in civil life as these returns show it to be in the army, and that its prevalence varies according to season and locality. I am of opinion, too, that liver abscess in the native has a somewhat different mode of origin, being exclusively due to climatic influence, and independent of habits of life. It occurs in the native as a late result of general constitutional decay from prolonged malarial poisoning. The subjects have invariably been exposed for a long period to malarial influence, and are the victims of a profound cachexia. In Europeans, on the other hand, the liver appears to be excited to inflammation under short exposure to local influence; more than 50 per cent. of the cases occur during the first four years of residence. The attack may be of a splenic type in the European, but it is low and insidious in the native. It is a more serious affair in the latter, and the mortality per cent. of those treated is higher. In a vast country like India climates of every degree of unhealthiness are to be found; and malarious districts, from topographical or meteorological causes, are subject to changes in the intensity of the endemic incidence. A notable example of such a phenomenon has occurred during the past ten or fifteen years in Bengal. Since 1870 a portion of that

[1] Read before the Middlesex Hospital Medical Society.

Digitized by Google

province has become decidedly more unhealthy from malaria. A kind of epidemic wave passed over the tract from north to south-west, involving in its course the district of Midnapore. The result of the invasion is that the inhabitants now bear the impress of the noxious influence in a marked degree, in the shape of enlarged spleens, anæmia, bowel complaints, and cachexia generally. Dispensary records also show an increase in admissions for liver abscess coincident with the increased prevalence of fever. While civil surgeon at Midnapore, I treated there, in the three years 1882-84, no less than twenty-one cases, all in natives. Local practitioners informed me that in former times the disease was practically unknown.

In Europeans the greatest liability occurs between the ages of twenty and forty-five. Abscess has never yet been met with in any person, native or European, below fifteen, and it is rare above fifty. In childhood it is absolutely unknown. Among Europeans men are more liable than women.

British Army in India, 1883. Hepatitis.

	Admissions per 1000.	Deaths per 1000.	Admissions per cent. of total admissions.
Men (54,000)	30	1·41	2·1
Women (3290)	15·5	·91	1·8

The disproportion is still more marked as regards abscess itself. In Waring's 300 cases 9 only were in women, and out of 82 cases reported in various journals 2 only were in women. On the other hand, out of 23 cases in Europeans and Eurasians treated at the Presidency Hospital, Calcutta, as many as 15 were females. The proportion of females to males among the British-born population in India is 1 to 7. I have reason to believe that owing to the exclusive climatic mode of origin in natives there does not exist the same difference in liability of the sexes as in Europeans. Among my 21 cases, mostly dispensary patients, 3 were females; and bearing in mind that the population of females to males attending dispensaries in Bengal is about 1 to 6, this, as far as it goes, does not indicate any very great irregularity.

Authorities are agreed that suppurative hepatitis in Europeans in the tropics is mainly due to the effect of climate. But intemperance, over-indulgence in animal and highly spiced foods, and indolence, are spoken of as predisposing causes in the individual; while exposure and chills are frequently noted as exciting causes. I am quite disposed to admit that chill or exposure starts the attack in many instances; this is clearly the mode of origin of many of the reported cases. But have we sufficient evidence of the part the other conditions play in the production of the disease? The great difference in the liability of the two races is attributed to the variation in the nature of diet and drink, but it may equally be due to difference in degree of acclimatisation. The great reduction in liver diseases in the army is as likely due to improved sanitary arrangements and protection against climate as to the steadier habits of the men. I am inclined to think that the "intemperate" theory, at all events, has been made too much of. An examination of reported cases throws very little light on the subject, because complete histories are so rarely given. It is a significant fact, however, that out of 425 cases of hepatic abscess, including Waring's 300 and others from the journals, the subjects were said to be intemperate in 50 instances only. Whatever influence personal habits may have, the fact remains that, quite independently of any of them, when an inhabitant of temperate climates goes to reside in the tropics, there is a tendency for his liver to become disorganised, though fortunately this actually occurs in a relatively small proportion only. This applies to the dark races as well. Natives of mountain regions in India, on taking up their abode in the steamy plains of Bengal, are said to become liable to hepatic abscess. Change of climate affects hill cattle in the same way. Imported horses suffer to a large extent; the death-rate from hepatitis among troop horses in India amounts to 2 per 1000 (Collins).

What is the particular element or combination of elements in a tropical climate that induces hepatic disease? It cannot be heat alone; liver abscess is least common in such parts as the Punjab, Central Provinces, &c., where there is greatest heat. Nor is it malaria alone, for the disease is unknown in malarious parts of the temperate regions of the world. The distribution of hepatitis according to district points to a combination of moist heat, dampness of subsoil, and concentration of malaria as the condition most favourable to its production. Still there is something over and above this in the climate of India that we do not understand. An exactly similar combination exists in the West Indies, though the disease is not so frequent there (in the proportion of 1 to 4).

Dr. Budd's now obsolete theory of the dependence of tropical abscess upon dysentery only requires a passing notice. It is unsupported by clinical observation, statistics, and post-mortem examinations. Dysentery being a disease caused by similar conditions of climate, very frequently complicates liver abscess, and a very serious complication it is, but there is no causal relation between the two. Their concurrence in the same individual is a pure coincidence. It is important to remember that the signs and symptoms even of the hepatitis that precedes it, and of the abscess itself, are apt to be ill marked and insidious; they often escape notice, or some or all of them may be absent. It has been estimated that they are well marked in 8 per cent. only, while the abscess runs a perfectly latent course in 13 per cent., even in Europeans. Instances are on record where the subjects were engaged in their usual occupations up to the very last. Soldiers have been on full duty up to a few hours of death by the bursting of an abscess internally. In one case an abscess burst while the man was actually on duty. The signs which in a given case of hepatitis lead to suspicion of suppuration are: The enlargement of the liver, which loses its uniform contour and develops more particularly in some one direction so as to form a bulging; localisation of pain and tenderness; pleuritic or peri-hepatitic friction; rigors, chills, sweats, and—most important of all—the temperature. Several apyrexial cases are on record, but I cannot conceive suppuration occurring without the temperature being affected at some time or other. A careful scrutiny of the temperature range, auscultation, and bilateral measurements of the chest are called for. The temperature must be taken every hour, so that a complete reading for the twenty-four hours may be obtained. Subjects of liver abscess are frequently also suffering from malarial fever. A want of periodicity and a resistance to quinine will indicate hepatic origin.

By combined statistics the mortality of unrelieved hepatic abscess is found to be about 90 per cent. Death occurs with or without rupture. About one-half of all abscesses that are left alone remain intact. Spontaneous evacuation through the lungs occurs in about 20 per cent., less than half of which recover. Out of 33 cases that recovered spontaneously (Waring's and others), 16 burst into the lungs, 8 into the intestine, 1 into the stomach, and 2 ended apparently in spontaneous absorption. The extent to which an abscess will develop is surprising. The contents are sometimes to be measured rather by quarts or gallons than by ounces. The whole organ may be converted into a bag of pus. In one case 17 pints were found at the post-mortem examination. I have myself removed as much as 80 oz. at a single operation; while 200 oz., 400 oz., and even 1000 oz. represent the aggregate amounts removed by successive tappings by others. These enormous collections are mostly seen in natives, who are apt to apply for treatment only at too late a stage of the disease.

Solitariness is a character of tropical abscesses, but they are often multiple. In Waring's 300 cases they were solitary in 62 per cent., multiple in 37·8 per cent. Multiplicity is explained by the mode of origin. The disease begins as multiple foci of softening. The foci coalesce as they increase in size. If the areas coalesce into one, a single abscess results; if they combine in groups, the abscesses will be multiple.

(To be concluded.)

TWO CASES OF ABDOMINAL SECTION.

BY A. S. UNDERHILL, M.D., M. CH., S.S. CERT. CAMB.,
SURGEON TO THE GUEST HOSPITAL, DUDLEY.

RECENTLY I have had two cases in which I performed abdominal section, and as these—although fatal—possess points of clinical interest I venture to record them.

CASE 1. *Rupture of a Tubal Pregnancy.*—M. I——, aged twenty-two, married eighteen months, one miscarriage at eighth week, a florid, healthy-looking woman, had catamenia regularly till seven weeks ago, when she was suddenly seized with acute pain in the abdomen, referred chiefly to the region of the right ovary, which continued for about

Digitized by Google

ten days, leaving her fairly convalescent at the end of two weeks. As she was feeling stronger, she walked for some little distance, but on her return home was again seized with the acute pain over the right ovary, became perfectly blanched, staggered to a sofa, and was profoundly collapsed for about twelve hours; from this condition she very slowly recovered, and still referred all her pain to the right side of the lower abdomen. On vaginal examination I found the os and cervix uteri œdematous and very tender, but unlike what is usually found in commencing pregnancy, the uterus was fixed and deflected to the right; posteriorly there was a tender semi-solid mass; abdominal percussion—as far as could be ascertained on account of the tenderness—gave a duller note than normal from the groin to the umbilicus on both sides. Her condition during the next twelve days was very unsatisfactory. She had a recurrence of peritonitis, and suffered most distressing pain. Her pulse was never under 140, and her temperature averaged 103° F. Neither herself nor relatives would consent to any operative interference. On the fourteenth day her symptoms became aggravated, and as she would evidently sink before many hours elapsed, permission was given for abdominal section.

On opening the abdomen in the mesial line about a pint and a half of very dark-coloured serous fluid gushed out. On the right side the uterus was bound down by adhesions and coagula to the brim of the pelvis. The right broad ligament was a mass of coagula, the Fallopian tube being much thickened and enlarged; the left broad ligament was encased in coagula, but it was impossible to recognise the Fallopian tube; the intestines at the lower part of the abdomen were matted together by inflammatory adhesions. To appearance and touch much of the coagula resembled placental tissue, but nowhere could I find a trace of an embryo. I removed as much of the coagula as possible without injuring the intestines, thoroughly washed out the cavity with warm water, and inserted a glass drainage-tube into the pelvis. She rallied well from the operation and suffered little pain. On the eighth day, however, she died, obstinate constipation and vomiting being the predominant symptoms.

In my opinion the patient had a right tubal pregnancy; the first attack of peritonitis killed the ovum, which burst after the exertion of walking, and so caused the hæmatocele. If at this time consent had been obtained for the operation her chances of recovery would have been more promising; but on the fourteenth day fresh bleeding took place and handicapped the operation, from which she had not sufficient strength to rally. Under similar circumstances I should not hesitate to advise an early operation, as I think I might promise a fair relief from pain and a probably favourable result.

CASE 2. *Cystic Degeneration of both Ovaries with an old Hæmatocele.*—M. C——, aged forty-two, married, with six children, nine months ago was attended by a midwife, who delivered her after a very severe labour. Some weeks afterwards, not feeling strong and suffering great bearing-down pains and pain in defecation, she consulted a medical man, and was treated by rest in the recumbent position and tonic medicine, but not feeling much better she was admitted under my care into the Guest Hospital. I found the uterus retroflexed, but fairly movable on the sound. Posteriorly, in Douglas's pouch, there was a tense swelling, somewhat caudate in shape and very painful on pressure. Per rectum it was more defined; over both ovarian regions there was considerable tenderness, so much so that it was impossible to ascertain their condition. She could not walk or stand without much bearing-down pain, and she had occasional attacks of obstinate vomiting; the temperature was normal. Permission to explore the abdominal cavity could not be obtained; I therefore treated her with morphia suppositories and mild aperients, keeping her entirely in bed, considering that hers was a case of pyosalpinx—very full—coming on after delivery. As she did not obtain the relief she anticipated, she left the hospital at the expiration of three weeks, but returned after two months, during which time she had had no cessation from pain, and had lost 12lb. in weight.

As the patient was now quite unable to do anything, and was evidently becoming worse, after consultation I performed abdominal section, and found the right ovary considerably enlarged and full of cysts; the left ovary was also in a state of cystic degeneration, and bound down firmly in the recto-vaginal cul-de-sac. On removing it, a small cyst which was adherent burst, its contents being lost in the pelvic cavity. On rectal examination, directly after its removal, the caudate swelling could still be felt, tense and firmly adherent, evidently an old hæmatocele, which had become partially absorbed, and was now organised. In both instances the Fallopian tubes were intact. I thoroughly washed out the pelvic cavity with warm water; and as hæmorrhage was very slight, I did not resort to drainage. She passed a fair night, but never completely rallied from the shock, and died twenty-eight hours after the operation.

No post-mortem examination was allowed, but I examined the wound, and found that there had been no bleeding; the stumps of the appendices were healthy-looking, and, as far as I could ascertain, there was no appreciable cause for her death except exhaustion. Had she consented to the operation when it was first proposed, I feel assured that her life would have been saved. I have twice operated on more seemingly unpromising cases with favourable results, but this patient was of a depressed, nervous temperament, and greatly dreaded the operation, making her on this account a very unfavourable subject. The case was of interest on account of its diagnostic difficulties, as the swelling was in shape, position, and history typical of what is usually found with pyosalpinx.

Tipton, Staffs.

A CASE OF RAPID PLEURAL EFFUSION TREATED BY ANTISEPTIC INCISION.

BY ALBERT WILSON, M.D.

THE following case is of interest, as it shows the advantage of an incision made during the early stage of pleural effusion before it had become a case of empyema. In fact, the effusion was so large and so rapid, and the dyspnœa and cardiac depression were so great, that the case would never have reached the stage of empyema if prompt operative treatment had been delayed.

The patient, Mrs. B——, aged thirty-five, was first seen by me on March 3rd, 1886. She complained of breathlessness and increased cough, and she had been ill nearly a week. There had been no rigors; the pulse was 140, small and weak; the expectoration was mucous, slightly rusty; respiration 40; temperature under the tongue 102°. On examining the chest, the left base was dull on percussion. The front of the chest was normal in all respects. Auscultation: At the right base there were moist râles and crepitations; at the left base there were no respiratory sounds audible; vocal resonance was increased over the right base, whilst it was œgophonic over the left base; vocal fremitus was increased over the right base, but absent over the left. The absence of vocal fremitus decided the diagnosis as pleurisy and pneumonia.

March 4th.—The dulness is higher posteriorly, and in the axillary line there is also dulness in front from the left side when she sits up. The first sound, which is weak, is loudest behind the sternum. Temperature 101°; pulse 140; respiration 46.

5th.—General condition worse and increased effusion. Absolute dulness at and below the third rib in front, and from a line parallel with the fourth dorsal vertebra behind. The right chest is normal, except for cardiac dulness over the fourth right costal cartilage. The apex of the heart is now almost under the right mamma. There is a total absence of respiratory sounds all over the left chest, both back and front, except above and just below the clavicle. Œgophony is well marked at the angle of the left scapula, the vocal resonance is altered in front, vocal fremitus is absent on the left side, and there are moist sounds over the right base. Temperature 101°; respiration 48; pulse 140. The pulse tracing shows a very small wave, due to the feeble cardiac impulse and the contracted arteries. Operative treatment was now imperative. Being a disciple of Lister, I did not feel justified in opening this large cavity without the spray, as it was a small foul room, and the impure air entering the pleural cavity would be very dangerous and certain to cause suppuration. Further, to wash out the cavity, which I had allowed to become septic, would be an unnecessary labour for me, and a needless and rather dangerous entertainment for the patient. I preferred prevention to cure. I made an incision between the seventh and eighth ribs posteriorly to the axillary line. Clear serum poured forth in abundance; more than five pints were

Digitized by Google

collected and about a pint was wasted. Air entered the chest freely. When I introduced my finger through the ribs, I could not reach the lung for at least half an hour after the incision was made. When the lung did expand the surface of the pleura was found to be quite rough. A tube four inches long was inserted downward and backwards, and I applied a small dressing of boracic lint soaked in mercurial solution. Within an hour the heart sounds were to be heard under the left breast. Friction was heard posteriorly as soon as the pleural surfaces were apposed. The friction gradually appeared from above downwards, as the expansion of the lung was very gradual, and when I left it had not fully expanded at the base, which I proved with my finger. The pulse tracings, taken every few minutes, were very interesting. Before the operation it was a slight deviation from a straight line, being so feeble. Soon after the operation the pulse wave expanded, getting larger and fuller until there was a full, sharp, apex systolic wave with a marked dicrotic wave, showing low arterial tension, due to the relaxation of the arteries and the removal of the pressure on the heart and main vessels.

6th.—Temperature 101°; pulse 120; respiration 32. The wound was dressed under the spray. There was a free serous discharge through the tube, and air enters with inspiration. The physical signs of pleurisy are well marked.

7th.—Temperature 101°; pulse 120; respiration 26. Wound dressed and tube removed. I inserted my finger to feel the pleura. It felt rough and spongy, like the placenta. I passed my finger round, separating the adhesions of the two surfaces, and it reminded me of a case of placenta prævia. It was the adhesion of the surface that determined me to remove the tube.

8th.—Temperature 101°; pulse 108; respiration 26.

10th.—Temperature 100°; pulse 98; respiration 24. Wound dressed. Very little thin serous discharge. Physical signs normal over both lungs. I could not trace the cause of the slow fall in temperature. The patient, though very weak, is doing well, considering that she was at death's door before I operated.

15th.—Temperature 99°; pulse 90; respiration 20. Wound dressed, and healing satisfactorily. Before the operation I measured each side of the chest from the anterior to the posterior mesial line just below the mammæ. The right half was 16 in., the left 17¼ in. To-day, five days after the operation, each side measures 16 in. alike. The spine is perfectly straight, and the left chest is not shrunken. These results could not be attained by aspiration, however skilfully done. The patient was soon restored to perfect health.

Leytonstone.

A CASE OF SUPPOSED FRACTURE OF NECK OF SCAPULA.

BY G. Y. EALES, M.R.C.S. ENG., L.R.C.P. ED.,
HOUSE-SURGEON, TORBAY HOSPITAL; LATE ASSISTANT DEMONSTRATOR OF ANATOMY AT ST. GEORGE'S HOSPITAL; AND SENIOR ASSISTANT-SURGEON, SIRHOWY IRONWORKS.

LAST September R. B——, aged fifteen, a spare, delicate-looking lad, came to me with an injury to the left shoulder. He was playing with several boys, butting at each other with folded arms, when he was knocked over and fell on his left shoulder. On examination I found the following points of observation:—1. Considerable bruising of the deltoid. 2. The acromion process prominent, with depression underneath, and outer third of the deltoid flattened. 3. Arm lengthened about an inch and a half, and drawn away slightly from the side. 4. A rough object high up in the axilla in the neighbourhood of the neck of the scapula. 5. Humerus rotated freely and smoothly, and with but little pain. 6. A round projection in front and below the shoulder, which proved to be the head of the humerus on rotating that bone. 7. On raising this projection upwards, outwards, and backwards, crepitus was produced; the contour of the shoulder was restored, with disappearance of the deformity. 8. Slight increase of vertical measurement around the joint. 9. Great freedom of passive motion, with but little pain.

Owing to the bruising I was unable to manipulate the coracoid process; I therefore put the arm up with a pad in the axilla, with the elbow raised and bandaged to the chest. Five days afterwards, the bruising and swelling having partially subsided, I took off the bandages and found the same condition of things as when I first saw him, but much more plainly. On raising the head of the humerus all the symptoms disappeared, accompanied by loud bony crepitus audible to the bystander; and on removing the reduction force all the above-named symptoms again appeared. I was struck with the ease and comparative absence of pain with which the fracture could be reduced, also the readiness with which it became displaced on removing the reduction force. The rough object in the axilla was now more distinct, and disappeared on reducing the fracture, and was apparently the scapular neck. I now noticed also that the coracoid process did not appear to move on reducing the fracture.

Remarks.—The noteworthy features of the case were (1) the ease with which the fracture could be reduced, together with the ensuing deformity on removing the reduction force; (2) the great freedom of passive motion; and (3) the striking resemblance to dislocation into the axilla. With regard to this latter, the lengthening of the arm, the freedom of passive motion, and the easy reduction of the deformity in the way I have mentioned were sufficient to exclude simple dislocation into the axilla. The other lesions which this injury simulates appear to be (1) dislocation of the humerus into the axilla, with fracture of its neck; (2) separation of the epiphysis of the humerus; and (3) dislocation of the humerus into the axilla, with fracture of a portion of the glenoid cavity of the scapula. The lengthening of the arm and the movement of the head of the humerus on rotation are against the first two. Holmes, in his System of Surgery, states that it is the opinion of most modern writers on surgery that a simple fracture of the anatomical neck of the scapula never occurs, and that Malgaigne has shown that the symptoms of the supposed lesion are identical with those of dislocation of the humerus into the axilla, with fracture of a portion of the glenoid cavity of the scapula. In another place Holmes admits that the two lesions are indistinguishable during life. I hardly dare to express an opinion in the face of such high authority; but why should not a simple fracture of the anatomical neck of the scapula occur as readily as the more complicated injury? because the force to produce either must be of the same nature and very considerable. It appears to me that the symptoms of this case are so analogous to those quoted by Dr. Lotzbeck of Munich[1] and that recorded by Spence,[2] and bearing in mind the fact of the coracoid process being apparently stationary, that I feel justified in saying that in all probability this was a case of fracture through the anatomical neck of the scapula.

The lad having passed from my care and observation for treatment by another surgeon, I am unable to give any details of the progress of the case, but I afterwards ascertained that he eventually gained very good use of the arm.

Torquay.

A Mirror OF HOSPITAL PRACTICE,

BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

WEST LONDON HOSPITAL.

ABSCESSES OF THE NECK AND BEHIND THE PHARYNX, ALMOST CAUSING DEATH FROM SUFFOCATION.

(Under the care of Mr. WAINWRIGHT.)

ABSCESS at the back of the pharynx is a very formidable disease, as is illustrated by this case, and requires the most prompt surgical treatment. The chief danger is that of suffocation, either from œdema of the glottis or the mechanical effect of the swelling. In this case the relief afforded by incision of the external abscess made it probable that the post-pharyngeal abscess communicated with it, but the subsequent progress of the case negatived this view.

[1] See New Sydenham Society's Biennial Retrospect for 1867-8, p. 240.
[2] Edinburgh Medical Journal, 1863.

Digitized by Google

Simple incision with a guarded knife is usually sufficient to relieve the symptoms; but occasionally tracheotomy may be required, as in a case which was recently under our observation, where the flow of pus from the abscess was so copious as to stop respiration. For notes of the following case we are indebted to Mr. R. Lake, house-surgeon.

On May 10th, 1886, an adult, G. H——, was admitted into the hospital suffering from attacks of dyspnœa. His voice was low and harsh, his face very anxious, and the breathing distressed, with frequent attacks of dyspnœa. On examination of the neck a large fluctuating swelling was found beneath the trapezius on the right side, and on looking into the mouth the pharynx was found bulged out on that side and pushed towards the left. There was much swelling in the right submaxillary region. He gave the following history: The swelling with pain began six weeks previously, and there had been gradually increasing dysphagia, so that for the last seven days he had only been able to swallow fluids. He had had syphilis five years previously, and some months ago a general eruption of rupial character broke out, from which he is still suffering.

An incision was made into the abscess under the trapezius, with antiseptic precautions, and about two ounces and a half of pus let out. This relieved the breathing, and it was hoped that the other abscess would be emptied through this. He was given ice to suck.

May 4th.—At 1.30 A.M. he had become much worse; the breathing stopped entirely for a few moments, and it required artificial respiration to bring him round. An examination was now made with the laryngoscope, and there was found to be a large amount of œdema of the right side of the pharynx and tongue, and a swelling on the same side involving the whole of the right side of the pharynx, and projecting beyond the middle line. This was incised, and about two ounces of fetid pus escaped. The symptoms were at once relieved, and when the patient spoke it was with a voice which was now full and clear.

12th.—A mixture containing ten grains of iodide of potassium was ordered, and he was placed on a diet of meat, and allowed stout. He was able to take solid food for the first time during nine days.

14th.—The incision in the pharynx had closed, and so was reopened, two ounces of glairy fluid escaping.

17th.—The dose of iodide of potassium was increased to twenty grains.

20th.—Much better. There is only slight discharge from the incisions.

27th.—The abscesses are quite healed, and the eruption on the body is rapidly improving under large doses of iodide of potassium.

STROUD GENERAL HOSPITAL.

TWO CASES OF EXTERNAL URETHROTOMY.

(Under the care of Mr. STORRY.)

CASE I.—Walter W——, aged twelve, was admitted on Feb. 26th, 1886. The boy gave a history of having fallen, some sixteen months ago, on some stone steps, the sharp edge of one step having caught him in the perineum. There was at the time of the accident considerable bruising and swelling of the perineum, and blood issued from the meatus on attempting to pass urine. He was unable to micturate, and a medical man was consequently sent for, who passed a gum-elastic catheter, and repeated this operation in a week's time. From this time up to the date of his admission the boy had not sought further advice.

On admission, the urine passed in drops, the boy crying out and straining severely; he complained also of a smarting pain at the back of the perineum. Several attempts were made by Mr. Storry and the house-surgeon to pass an instrument, but without success. External urethrotomy was therefore decided upon, and on March 2nd the patient was etherised with one of Clover's small inhalers; and before operating Mr. Storry tried again to pass a catheter, but this was impossible. Mr. Wheelhouse's grooved straight staff, with the beak turned up as a blunt hook, was passed down to the stricture; the urethra was opened upon the staff, and the sides of the divided urethra being held apart with forceps, the small probe-pointed director was after considerable difficulty passed into the bladder. The strictured portion of the urethra was then divided, and the tapering probe-pointed gorget introduced above the director into the bladder; a No. 8 silver catheter was passed through the meatus upon the gorget into the bladder, and the catheter tied in. This catheter was left for ten days, when a No. 9 silver was passed, the perineal wound having healed by this time. After this a No. 8 silver was passed daily, which after a time was changed for a No. 9.

The boy was discharged on April 12th, a No. 10 silver catheter being passed the same morning. He was told to return in three or four days, but failed to do so until a fortnight afterwards, when a catheter could not be then passed, so he was readmitted for a day or two, and was taught to pass for himself a No. 7 gum-elastic catheter.

July 19th.—He passes easily a No. 7 gum-elastic catheter every morning before going to work at a stick-mill in his neighbourhood.

CASE II.—Thomas W——, aged sixty, was admitted April 7th, 1886. The patient had gonorrhœa in the year 1855. He was for three months under treatment. He says "it gathered" at the time in three different places in the spongy portion of the urethra. After this he had no other attendance until 1886 when he suffered from retention and œdema of the penis and scrotum, and was admitted as an in-patient of this hospital. He then had catheters passed. For three years, at the least, he has had a fistula in the perineum and one at the inner part of the right thigh, and for two years he has had another fistula by the side of the frænum preputii.

On admission, the last three inches of the spongy portion of the urethra was of a cartilaginous hardness. Urine came only from the three fistulæ, none by the meatus. There was a deep cicatrix involving the lips of the meatus, through which a No. 1 silver catheter could be passed about a quarter of an inch.

April 13th.—The patient was placed under ether and a way into the urethra was attempted by the meatus, but a very fine probe only reached about a quarter of an inch. An attempt was then made to get at the urethra by means of the fistulous opening by the side of the frænum preputii, but this failed also. An incision was now made in the central line of the perineum through tissues which cut like cartilages, and after great difficulty the proximal end of the urethra was found, but after half an hour's searching the distal end could not be seen or reached. Mr. Storry then prolonged the incision in the left lateral lithotomy line and entered the bladder. The hæmorrhage was very slight. The patient was then taken back to bed, the urine for four or five days passing by the lateral incision. Several attempts were made to pass a catheter by the meatus, and at last one was passed about four inches.

27th.—The house-surgeon was successful in passing a No. 9 silver catheter, after having introduced several smaller ones through the meatus into the bladder. This was tied in for twenty-four hours, and the following day a No. 4 silver was passed and tied in, but this had to be removed on account of the pain and irritation it caused. For three days no instrument was passed; but on the 4th of May a No. 8 silver was passed pretty easily; a day or two later it was passed again, and the patient himself was instructed to pass a No. 5 gum-elastic for himself. The wound in the perineum by this time was healing rapidly, and no urine flowed by the fistulæ.

June 7th.—The sinus on the inner side of the thigh was laid open and scraped; the incision in the perineum has nearly healed, and the patient passes for himself a No. 6 gum-elastic easily.

21st.—The sore on the inner side of the thigh has healed, the fistula by the side of the frænum also is closed, and there is only occasional slight weeping from the perineal fistula. The patient was discharged to-day, being able to pass for himself easily a No. 7 gum-elastic catheter.

MATER MISERICORDIÆ HOSPITAL, DUBLIN.

CASE OF SPONTANEOUS CURE OF OVARIAN TUMOUR.

(Reported by Mr. C. H. CALLANAN; clinical assistant.)

MARY C——, aged twenty-nine years, was admitted on May 21st, 1886, suffering from ovarian tumour, which caused her great inconvenience, and had been undermining her health for some months past. She had been married two years, but had no family. Three months ago she consulted Dr. Duke, of Steevens's Hospital, for a swelling over the right ovary. It was excessively tender and painful, and gradually increased in size until it extended over the

Digitized by Google

abdomen. Steevens's Hospital being closed, she was taken into the Mater Misericordiæ Hospital, and seen by Dr. More Madden, the obstetrical physician, who considered the case one for immediate operation, in consequence of the delicate state to which the woman was reduced in a short period and the intense degree of pain caused by the tumour. A few days after her admission the patient was seen in consultation by Dr. More Madden, Dr. Duke, Mr. P. Hayes, and Dr. Boyd, all of whom agreed that the case was one for ovariotomy, the diagnosis being a thin-walled, globular, well-marked multilocular ovarian tumour. The abdomen then measured 43½ in. in girth. Being close on the menstrual period it was decided not to operate until this should have passed, and it was accordingly postponed until June 15th, tonics being administered to increase the woman's strength. She was up and going about the ward, but on June 9th she took to her bed, complaining of intense abdominal pain. After some hours the pain was followed by incessant diarrhœa and profuse diuresis, which lasted four days. At the expiration of this period the abdomen was found to have considerably decreased and no trace of the tumour was discernible. The patient was again seen in consultation by the before-mentioned gentlemen, including Dr. Byrne. All concurred that spontaneous rupture of the cyst had taken place, with effusion of the ovarian fluid into the peritoneal cavity, its absorption thence, and evacuation by the bowels and kidneys. After this the patient gradually improved. An examination was made on June 16th. Some fluid was still discernible in the peritoneal cavity, but the abdominal pain and soreness were greatly reduced. To relieve the pain and help the absorption, an ointment made up of extract of belladonna and mercurial ointment was rubbed over the abdomen, and a mixture of iodide of potassium given, which she had been taking some time previously. The patient remained in bed about fourteen days, recovering both health and strength. The abdominal swelling had gone down to 29 in. The woman finally left the hospital on July 15th, and was again seen after a week, when she was in excellent health and spirits, being about to take a journey to the country.

ST. JOSEPH'S HOSPITAL, VICTORIA, BRITISH COLUMBIA.

ANEURYSM OF THE INNOMINATE ARTERY; SIMULTANEOUS LIGATURE OF THE COMMON CAROTID AND SUBCLAVIAN ARTERIES; HEMIPLEGIA; DEATH.

(Under the care of Mr. E. A. PRAEGER.)

S. B——, a Frenchman, aged sixty, applied for advice on Jan. 26th, 1885, giving the following account of himself. Family history very good. Has never had any serious illness. Had gonorrhœa years ago, but never had syphilis. Has been a gold miner and has done a great deal of "packing" goods to and from the mines. Two years ago a heavy weight fell on his chest. Shortly afterwards he noticed a swelling on the right side of the chest, between the first and third ribs. The swelling has gradually increased in size. Feels an oppression when he draws a long breath. Has a cough, which has only existed the last month or two, and expectorates a little bright blood occasionally. When he walks fast or goes upstairs, he experiences a feeling which he describes as "like palpitation of the heart, under the swelling." Sometimes when walking in the street he is seized with dizziness and inability to breathe, and has to catch hold of anything at hand to prevent himself from falling. Complains of constant pain at the back of the right shoulder and in the chest, under the swelling. Has a constant numbness in the right arm and hand, and says the pain is so bad that he is unable to sleep at night.

The patient's condition on examination was as follows:—Muscular, but not fat. There is an expansile pulsating tumour extending from the right sterno-clavicular articulation to the second intercostal space. The first and second bones of the sternum and the sternal ends of the corresponding ribs are bulged forwards. A loud rasping bruit is distinctly audible all over the upper part of the right side of the chest. Pulsation in the right radial is hardly perceptible; strong and regular in the left. On pressure being made over the subclavian artery the symptoms are modified. Heart sounds normal. The man was ordered fifteen grains of iodide of potassium three times a day and a low diet. This treatment was continued for some weeks without benefit. At the request of Mr. Praeger the patient was carefully examined by Surgeon-Major Harrison, A.M.D., and Staff-Surgeons T. Canning Hickey and J. Lyon, R.N., who concurred in the diagnosis of aneurysm of the innominate artery.

The man was so anxious that operative measures should be adopted for his relief, although the immense risk attending surgical interference was fully explained to him, that with the consent and valuable assistance of the gentlemen above-named, it was determined to ligature the common carotid below the omo-hyoid and the subclavian in the third part of its course. He was accordingly admitted into hospital, and, on March 26th, chloroform having been administered by Dr. Hickey, an incision parallel with the anterior border of the sterno-mastoid was made through the skin and superficial fascia. The deep fascia having been scratched through with the finger-nail, the artery was reached. At this stage the patient vomited, which caused slight delay, but eventually the aneurysm needle, threaded with strong carbolised gut, was passed from without inwards around the artery, and it having been ascertained that nothing but artery was included, the ligature was applied and pulsation in the temporal artery was found to have stopped. Neither the jugular vein nor the pneumogastric nerve came into view. The wound was sponged with carbolised water and drawn together with silver wire sutures. The patient's shoulder being depressed, an incision was then made in the usual way by drawing down the skin and dividing it on the clavicle. While making this incision the patient vomited, and two small superficial veins (which it was the intention to avoid) were accidentally cut across, and caused great difficulty in securing them. A second incision was then made upwards at right angles to the first, and the deep fascia having been torn through with the finger-nail, the subclavian artery was felt for, and the aneurysm needle, threaded as before, passed around it, and the ligature applied. Pulsation was found to be wanting in the radial artery. The brachial plexus was felt, but the subclavian vein was not seen. The edges of the wound were brought together with silver wire, and the arm having been enveloped in cotton-wool, the patient was removed to bed. Pulsation in the tumour was hardly perceptible. The patient soon rallied from the shock, and complained of pain in the neighbourhood of the operation wounds only. 9 P.M.: Very feeble pulsation was felt in the right radial, none in the temporal, strong and regular on the left side. Temperature in the left axilla normal, in the right 96°. He was perspiring profusely. A subcutaneous injection of a quarter of a grain of morphia was given.

March 27th.—Slept fairly well, but has been vomiting and retching violently. Temperature normal in both axillæ. Pulsation in tumour very much diminished, no bruit. Pulsation in right radial rather stronger than last night; hardly perceptible in the right temporal.

28th.—Temperature normal in both axillæ. Pulse 92. Very much stronger in the left than in the right radial. Not properly established in the right temporal. Pulsation in the tumour hardly perceptible.

29th.—Temperature normal. Pulse 72. Feeble in left radial; more so in right. Has difficulty in swallowing; complains of pain in his head; cannot protrude his tongue properly; his speech is thick and he appears deaf. Pupils contracted.

30th.—During yesterday the left side of the face became paralysed, and during the night the left side became hemiplegic. Temperature normal. Pulse 84, becoming stronger in the right radial, but not so strong as in the left. Still complains of pain in the head. Is quite conscious; converses sensibly, but with thick utterance.

April 1st.—Operation wounds have healed by first intention; hyperæsthesia of left side.

May 3rd.—Less hyperæsthesia; passing large quantities (several pints) of urine of low specific gravity (1005); acid, no albumen.

Aug. 10th.—The quantity of urine has steadily diminished under ergot. Complete loss of sensibility and motion in the left side.

Feb. 20th, 1886.—Has continued in much the same state; eats and sleeps well; has recovered sensibility, but not power of movement in the left side.

March 10th.—Caught cold a few days ago; had bronchitis, followed by exhaustion, to which he succumbed to-day—a year, less a few days, from the date of operation.

Remarks by Mr. PRAEGER.—I greatly regret that, owing to a mistake on the part of the hospital porter, no post-

Digitized by Google

mortem examination was obtainable. The diagnosis arrived at was that the aneurysm was innominate, possibly subclavio-innominate, but that the aorta was not involved. Judging from the rapidity with which circulation was re-established in the right arm, it is probable that the first part of the subclavian, with the thyroid axis, was abnormally dilated. On several occasions previous to the operation, the patency of the vessels to the brain had been tested by making pressure on the right and left carotids together and singly, and after reading the article, written by Mr. Barwell, on this class of cases, this was considered one suitable for operation. Although the patient subsequently became hemiplegic (probably from failure in re-establishing the cerebral circulation), the symptoms of aneurysm gradually subsided, and there is little doubt that the operation succeeded in prolonging his life.

Reviews and Notices of Books.

An Introduction to General Pathology. By JOHN BLAND SUTTON, F.R.C.S. London: J. and A. Churchill. 1886.

IN this handsome and well-illustrated volume we have not only to welcome the work of a new writer, but, what is equally gratifying, to receive in it an abundance of new facts added to the pathological store. When, at Mr. Hutchinson's suggestion, the Pathological Society of London undertook to investigate more thoroughly than had ever before been attempted the diseases of animals, and had obtained with this object the co-operation of the Zoological Society, the services of Mr. Bland Sutton were secured, and in the main the facts recorded in the work before us have been gathered by him in the course of his five years' steady and unflagging pursuit of the objects which the Pathological Society had in view. The Transactions of that Society have been enriched by many communications from Mr. Sutton; but we venture to think that this further publication, which embraces so considerable a range, will astonish even the members of the Society, who have already been witnesses of the thoroughness and zeal with which he has pursued his researches. The gist of the contents of the volume was given by the author in his Erasmus Wilson Lectures at the College of Surgeons last spring; but it is needless to say that the topics there treated have received fresh illustration and considerable expansion here. The work is divided into five sections: the first, dealing with aberrations of nutrition, illustrates the subjects of hypertrophy and atrophy, correlation and degeneration; the second treats of inflammation and its results; the third is devoted to the cystomata; the fourth to neoplasms; and the concluding section reviews the subject of evolution as influenced by pathological processes. To adequately treat of such subjects in respect to the animal world, the writer must be as much a naturalist as a pathologist, and undoubtedly the present author presents just this combination. Such chapters as those on correlation and on the cystomata exemplify this, whilst the predominant idea of the work is the explanation of pathological facts by means of the evolution hypothesis.

Although for the most part the work consists of an aggregation of original observations upon facts of pathological interest in the animal world, there are not wanting pages in which the author shows that he possesses to a marked extent that great gift of generalisation which is so essential in the collation and comparison of individual facts. Perhaps the best instance of this is to be found in the chapter upon Inflammation, where Mr. Sutton boldly assigns a *rôle* to the ubiquitous leucocyte which far outstrips the conception of Cohnheim. For whereas that much-lamented observer and acute thinker was content to attribute the phenomena of inflammation mainly to deterioration of the delicate tissue of the vessel wall, Mr. Sutton, by a skilful use of the most recent discoveries of intercellular digestion and the phenomena of tissue-resorption as observed in the metamorphosis of the amphibian, sees in the white blood-corpuscle an active (we might almost say a combative) body which is stimulated to increase and multiply for the purpose of resenting injury and preventing the intrusion of foreign matter into the living organism. The conception is one which dazzles as much from its simplicity as from the ideas to which it gives rise, opening up suggestions in the direction of explaining the nature of so-called specific inflammatory neoplasms, and capable even of extension into the wider field of all new formations. Great as has been the dignity of the leucocyte hitherto—indeed, its amœba-like characters long since fascinated some naturalists, who endowed it with a special individuality,—it has certainly never been assigned so wonderful a *rôle* as Mr. Sutton would fain have us admit it to possess. We may nevertheless commend the study of this chapter as one full of suggestiveness to those who desire to extend our notions of pathological processes a little beyond their mostly too confined limits.

The chapters devoted to the Cystomata are full of interesting facts well marshaled. They go far to fill up a distinct lacuna in our knowledge. Indeed, the subject has never been adequately treated hitherto in any English text-book; for Virchow's classical description in his great (but unfinished) work on Tumours is not available to the English-reading student. Again, thanks to many observers, and largely to the author of this book, very material additions have been made to the subject, especially as concerns cysts in connexion with the reproductive organs; so that we venture to think that subsequent writers will be under great obligation to him for what he has done in this direction.

As to the chapters on Neoplasms, it must suffice here to say that Mr. Sutton is an ardent adherent to Cohnheim's doctrine of "tumour-germs," and that he adduces very numerous instances of various kinds of new growth in all varieties of animals which bear largely on that doctrine. Especially to be mentioned are the examples of teratomata, where, again, we find many new paths opened up, and advantage taken of the knowledge afforded by embryological research. Indeed, the book is one which will well repay careful study; and the fact that it is the product of one of our younger pathologists is encouraging, not only because it is written in the true scientific spirit, but because it is of good augury for many future contributions from the same source.

Il Clima di Roma. Conferenze fatte nella Primavera del 1885, inaugurando l'Istituto d'Igiene Sperimentale della R. Università di Roma. Con una Carta Topografica e Geologica dell' Agro Romano, e cinque Tavole illustrative. Por CORRADO TOMMASI-CRUDELI. (*The Climate of Rome.* Lectures delivered in the Spring of 1885, at the opening of the Institute of Experimental Hygiene in the Roman University. With a Topographical and Geological Map of the Agro Romano, and five illustrative Plates. By Dr. CONRAD TOMMASI-CRUDELI.) Rome: Hermann Loescher and Co. 1886.

MEDICAL climatology has made advances of which the importance could not be better appreciated than by comparing the present work with that published on the same subject by Sir James Clark half a century ago. Dr. Tommasi-Crudeli comes to his task equipped with accomplishments which were hardly considered as within the medical province in his distinguished predecessor's time. Himself an original authority in physiology and pathology, he possesses a knowledge of the earth's crust, its flora and its fauna, the waters that permeate it, the winds that sweep it, such as more than fulfil the Hippocratic ideal. So qualified, he has made a special study of the climate of Rome, and the results of his successive monographs on the subject are revised and condensed in the present volume.

When we talk of the Roman climate we cannot dissociate the theme from its distinctive characteristic—the malarial

Digitized by Google

poison. What is this poison? Till the researches of Tommasi-Crudeli and Klebs, published in 1879, the most plausible answer was that of Dr. Léon Colin, who defined it as an "intoxication tellurique," an earth-poison generated by the surplus vegetative energy of an abnormally fertile soil, whose fecundity was very partially absorbed by the scanty sprinkling of herbage that overspread its surface. Cultivate this soil, render to this vegetative energy its appropriate pabulum, and you provide the antidote to malaria. Such, stated with extreme brevity, was the theory of Léon Colin, embodied in a work of great ability, which, appearing as it did at the outbreak of the Franco-German war, encountered a public too preoccupied to give it the study it deserved. Tommasi-Crudeli combats this theory. He denies that the Roman Campagna possesses anything like the exuberant fecundity with which it has been credited. Its really fertile tracts are few and far between, rarely compensating the agriculturist for his labour—as, indeed, was well known to ancient husbandmen. Then, again, if the poison were gaseous, as Léon Colin's theory implies, the malaria-surcharged atmosphere ought to be at its maximum at noon-day, when the exhalation from the soil is greatest; but, on the contrary, the localities in which malaria is most pronounced reach their maximum of danger in the morning and evening—those periods of the day when the difference of temperature between earth and atmosphere renders the ascending aerial currents most powerful and most apt to transport the material of the poison. That material, according to Tommasi-Crudeli, is a living ferment, encountered equally on the mountain and the plain, in dry soils and in humid. Its existence was suspected and unscientifically described as long ago as the decline of the Roman Republic by the agriculturist Varro, and its nature and form are defined by Tommasi-Crudeli as a "Schizomêtês bacillaris." For its development it requires a temperature not lower than 20° C. (a moderate degree of humidity) and the immediate contact of the atmosphere with the soil it infects. As the absence of a single one of these conditions prevents the development of the malaria, so certain localities exhibit at times a natural suspension of the poison. In winter, for example, the fall of temperature below the required 20° causes a thermic suspension; the loss of the necessary humidity under prolonged drought causes a hydraulic suspension; and the interposition of sheets of water or of a thick matting of turf on the laying down of a pavement, by preventing the immediate contact of the atmosphere with the infected soil, produces an atmospheric suspension of the malaria. All this argument is worked out with great clearness and force of style in the fourth and fifth lectures, which may be recommended to the teacher or lecturer as models of what academic exposition ought to be.

The various modes of clearing the Roman climate of malaria are examined in much detail, and cannot but interest the practical hygienist who has to deal with similar problems elsewhere. One striking demonstration, in which Tommasi-Crudeli's proficiency as a classical scholar and archæologist comes into play, is that of the immunity from malaria enjoyed by Rome, under the *régime* of the Antonines, whose system of cunicular drainage, whereby the hydraulic suspension of the poison was attempted, was at once ingenious, laborious, and—but for its premature discontinuance—efficacious. Beautifully executed illustrations of the process supplement the author's exposition, and are the next best thing to a personal visit to the spots where excavation has brought the works to light. Other specimens of his power of evoking and rewarding attention are his criticism of Lancisi's doctrine of the causal relation of stagnant water to malaria—the "palustral prejudice," as he calls it,—and his exposure of the same eminent physician's fallacies on the influence of forest-planting as a protection from the poison in its alleged transport by the wind. But on these subjects we have already, in other departments of the journal, summarised the author's conclusions, and we refer to them now as having received his latest touches in answer to the animadversions of recent critics. Notwithstanding its localised theme, the book leaves no vital phase of meteorology untouched, so that its publication in an English dress would be a genuine boon to the profession at home and in the colonies. Messrs. Loescher, we may add, have done their part most creditably. The excellence of the plates and of the maps, particularly the fully-detailed and finely-coloured geological and topographical chart of the Agro Romano, are quite in keeping with the almost sumptuous finish of the paper and typography.

Chemistry of the Carbon Compounds; or, Organic Chemistry. By Professor VICTOR VON RICHTER, University of Breslau. Authorised Translation from the Fourth German Edition, by EDGAR F. SMITH, Professor of Chemistry, Wittenberg College, Springfield, Ohio. London: Henry Kimpton. 1886.

LET us begin by admitting that Professor Smith has done good work in translating Professor Richter's well-known text-book. It was wanted, for, alas, German is still an unknown tongue to many, and we have no English equivalent to Richter. The translation, and we may add the printing, of the American edition are excellent, and any faults we may find are personal to the German author. Fault-finding, however, is not our primary duty here. Organic chemistry is now such a huge growth that no ordinary text-book can adequately represent it. Of late real knowledge has been gained of the constitution of carbon compounds, and the rapid growth of the so-called organic chemistry has been mainly due to this study, and to the development of a symbolic notation by which its results are expressed, and indeed constantly anticipated. A structural formula is at once an explanation and a prophecy, for when once we know the structure of a compound, its synthesis generally follows as a matter of course. The artificial production of alizarin is a case in point. If we knew the structural formula for morphine we should probably be able to prepare it without the assistance of the poppy. Now, Professor Richter's book of over 700 pages, much of it printed in small type, is mainly devoted to classification and structure. An immense number of compounds are included, and the most modern views of their constitution are stated. The book covers the whole range of organic chemistry, and we have only to look it over to realise the enormous extent of the science. Short descriptions—generally very short, and even meagre—are given of each compound, and the general effect of the whole is that of a *catalogue raisonné*, rather than of a manual for practical use. The book is extremely valuable as an adjunct to others, but alone it would be useless to anyone. Of experimental detail there is very little indeed, and condensation is carried so far that in some cases it would be hardly possible even for a trained chemist to carry out the operations alluded to in the text. Nevertheless, every chemist will use it, and will only regret that it was not twice as large as it is. We are glad to see that the trimethylene and tetramethylene groups, so important as intermediaries between the paraffins and the benzene series, receive fair recognition.

THE FEMALE MEDICAL AID ASSOCIATION.—At Simla, on Sept. 29th, a meeting of the above Society was held, under the presidency of Lady Dufferin. An account was given of the useful work done by the Association, and an appeal made for funds to warrant a widening of the scope of its operations, in honour especially of the Queen's jubilee next year.

OF
INTRODUCTORY LECTURES
DELIVERED AT
MEDICAL SCHOOLS OF LONDON AND THE PROVINCES
AT THE
Opening of the Session 1886-87.

ST. GEORGE'S HOSPITAL.

INTRODUCTORY ADDRESS BY DR. WADHAM,
SENIOR PHYSICIAN TO THE HOSPITAL, AND DEAN OF THE MEDICAL SCHOOL.

AFTER welcoming his audience, and especially the new students, Dr. Wadham described the additions and improvements which had been made in the school premises, the increased facilities which had been provided for the study of physiology, and the appointment of Dr. Delépine as special physiologist. Those who knew him, and had already worked under his supervision, would, he said, recognise in his name a guarantee as to the efficiency with which this subject would now be taught, and would find that, for practical work and teaching purposes, the physiological laboratories of the school would be as complete as the most exacting students could require. He then alluded to the competition which was taking place between the medical schools of London and the system of offering entrance scholarships, saying that bold advertisements and offers of pecuniary advantages were superseding the attractions which formerly hung like a halo round the names of men of reputation and experience, and that the old feeling which made a man regard his school as his *alma mater* was threatened with extinction; that students were being bribed to enter the schools; and that there seemed to be a growing tendency to make medical education, like medical advice had long become, a gratuitous gift to all who sought it. He warned the students that the medical profession was comprehensive and difficult beyond most others, that it required for its study more than average abilities and energy, and that, in order even to master the scientific portion of it, they would have to make use of their brain as well as their memories. In advising them as to their conduct, he said: "Remember the oft-repeated boast of Mephistopheles, 'how little beyond devilish opportunity is needed to make men sin,' and keep out of the way of temptation. Above all, neither forget nor be ashamed of the religious and moral principles in which you have been reared; these are the connecting and preserving bonds of civil society, the source of all good and much happiness, and our best comforters in those days from which no man can expect wholly to escape, when the clouds obscure the sun, and all seems dark and desolate before him. You will require them also as safeguards against the temptation to idleness, and perhaps worse, by which, in common with all young men living in large towns, you will find yourselves constantly surrounded—dangers against which neither the care nor the advice of others can shield you, and which can only be avoided by the possession of those good principles which, I trust, have been bred in your bone and burnt into your blood as the richest heritage your parents could give you."

In referring to the difficulty students experience in passing their numerous examinations in the four years supposed to be sufficient for that purpose, the lecturer said, "As a rule, I should say that this is only done by students of exceptionally good abilities and memories, and only by such of them as have the good fortune not to fail in any of their examinations. It would, I think, be better to recognise this fact and extend the period of study for at least another year. This would be fairer to parents, who are now systematically deceived as to the length of time their sons have to remain at the schools, and would be a decided relief and advantage to the latter. The authors of the conjoint scheme appear to have some inkling of this, for they invite students to present themselves for examination in several subjects immediately after registration. In other words, they invite, but do not compel, them, before entering the medical schools, to study chemistry and physics, and pharmacy and materia medica, in the latter case putting the horse behind the cart, and asking students, before they know anything of disease, to come and be examined as to their knowledge of the medicinal action of the agents used for its relief. The effect of this regulation is either that students are crammed in these subjects beforehand, or else have to commence their studies with an amount of work which they ought to get through in their first year, and which they can only accomplish by a process closely allied to cramming here. In this manner they learn an innumerable number of facts, but have no time to assimilate or coördinate them. They acquire information, but not knowledge, not even the knowledge of how to put this information to practical account. This information they deliver over to their examiners as much as possible in the very words in which they received it from their teachers, and, unless gifted with very good memories, forget it immediately. To borrow a very old illustration, it is as if sheep were to vomit up the very grass itself which they have cropped and swallowed, to show how much they had eaten, instead of concocting it into wool and milk. The regulation is also unfair to the schools, for it obliges them to maintain a staff of teachers upon subjects which students are allowed, if not encouraged, to study elsewhere. Unless a student by the end of his first year is successful in passing his examination in all these subjects, with the addition of elementary anatomy and physiology, he has either to sacrifice his next winter session in getting them up, or else to study higher anatomy and physiology, and to dissect, at a time when his mind is busy with some or all of these subjects. In either case the result is that he falls behind with his work, and probably takes nearer six than four years to obtain his qualification to practise. It is true that an attempt has been made to bring the examinations within the capacity of students by issuing synopses as to the range of most of the subjects, and allowing them to take them up one at a time. The privilege has also been lately granted of allowing students to postpone until the second stage of their examination the subjects of pharmacy and materia medica. By this arrangement the student, even without being once rejected, has to appear nine times before his examiners in order to obtain the double qualification under the conjoint scheme. These synopses, however, are either so obscurely worded as to render their meaning difficult, or else some of them are of such a nature as to be only imperfect guides to students, and can hardly be said to bind the examiners at all. For instance, in the case of the synopsis relating to elementary physiology, we find that although the varieties of connective tissue which have to be learnt are carefully marked, yet those of epithelial, muscular, and nervous tissues are not mentioned. The teacher is therefore obliged to demonstrate all the varieties of these in order to cover the whole ground. This brings us to the fact that at the end of his first year a student is supposed to know all the elementary tissues of the body and their varieties, with the exception of a few varieties of connective tissue. It seems, also, an anomaly to tell the unfortunate first-year student—as he is told in the synopsis—that the anatomical knowledge required of him is merely an acquaintance with the bones and the attachment of the muscles to the bones of the upper and lower extremities, and at the same examination to ask him to enumerate the principal changes which the food undergoes in the mouth, the stomach, and intestines, to explain, in fact, the function of organs with which he is anatomically unacquainted—a subject about which he can know nothing except as an effort of memory. This, I suppose, is the necessary consequence of dividing into two parts the examination in that which is really one science—a proceeding no more reasonable than it would be to divide astronomy into two sciences, one teaching the figure and size of the heavenly bodies and the other their movements.

"If I have detained you so long with all these details, it is because I consider that some reform is needed in the present system of examinations, and that the studies of the first-year student should be made less burdensome. These synopses should also be made clearer and more definite, should indicate all the questions that can possibly be asked, and, in addition to being a guide to the student and teacher, should be binding on the examiners. I believe, however, that the best reform would consist in an extension of the period of study; and in obliging the student to pass an

Digitized by Google

examination in such subjects as chemistry and physics, and pharmacy and materia medica, excluding therapeutics, before he enters a medical school, or, at least, before he commences the study of human anatomy and physiology. If animal and vegetable biology were substituted for pharmacy and materia medica, which latter concern the chemist more than the physician, and therapeutics were included in the examination in medicine, it would, I believe, be a better arrangement, an improvement in the student's education, and facilitate his subsequent studies. I also think that the examinations in elementary anatomy and physiology might with advantage be abandoned. These repeated examinations worry the student and interrupt his work, and are merely tests of his progress which might be much better carried out by the school authorities. Should the conjoint board ever take this view of the subject, they would find the materials for teaching ready to their hand at the London University, in the arrangements of some of the larger schools, and in that which we, in common with some of the smaller schools, have made with the Normal School of Science at Kensington. In this manner students would have time and facilities for studying and understanding subjects which they now only get up by memory for examination, and a check would be put to the pernicious system of cramming, without which no ordinary student can now get through his examinations in the time allotted to that purpose. The period of study being thus prolonged, the expense of medical education would be apparently increased. This increase, however, would be more apparent than real, for the intelligent student from choice and the dull one from necessity invariably occupy more than the conventional four years in acquiring even the rudiments of their profession."

In speaking on the subject of the discipline of medical students, and the proposal to attach colleges to each of the medical schools, the lecturer said: "I believe that in the treatment of the subject the public have not used the wisest method of arriving at a just conclusion. They have placed theory before experience, and the visionary before the practical, and in forming their opinion have been influenced more by their feelings and sentiments than by their reason and judgment. Many, too, who have written on the subject have evidently had no intercourse with students, and are ignorant of their disposition and feelings. At present I have neither read nor heard any argument in its favour which my own knowledge and experience do not enable me to refute. Few men have seen more of students than I have. I have known them living under the roofs and protection of their parents; in small parties under the care and supervision of gentlemen of upright character and having a full sense of their responsibilities towards them and towards their parents; and I have known them living in lodgings free from all control. I can honestly say that the last of these students were as a rule quite as good as the first, and that my experience of the result of associating students together has been anything but encouraging to an extension of that system. So far as my experience goes this tends far more to idleness and gossiping and card-playing than to habits of industry and study; and not unfrequently in these small coteries the evil influence is stronger than the good. Some of those who have proposed the foundation of these establishments have probably done so from an amiable desire to secure for the medical student the advantages of the collegiate system as it exists at the two Universities, and probably in ignorance of its many drawbacks even there. They have, however, overlooked the fact that these colleges exist as the result of past liberality and benevolence, and that the authorities by whom they are managed are supported by funds derived from the same source. Here they would have to be built and managed upon such conditions as would make them successful mercantile enterprises, and this I hold to be impossible except at an expense to students greater than their parents would be prepared to pay. The fact is also ignored that the most important factor in the success of the University system is, not that the students themselves are much controlled, but that the authorities possess the power of controlling and suppressing throughout a considerable district many of the temptations to idleness and dissipation and vice which exist, unchecked and uncontrollable, in this metropolis. What advantage would there be in 'gating' a student in this town at ten or nine, or even eight in the evening? Long before that hour, if so disposed, he would find time and opportunities to commit all the sins in the Decalogue, and a good many indiscretions outside it. The success and character of a student depend much more upon his early training than upon any other circumstance. If his parents have brought him up to be industrious, in the principles of virtue and honour, and with a love of truth, he will succeed and prosper in whatever situation he is placed, and the earlier he is encouraged in habits of self-reliance and independence the better he will be fitted to withstand the temptations and accept the responsibilities inherent to his profession. If, on the other hand, his parents have failed in their early duties towards him, no amount of supervision or discipline to which he can be submitted here will compensate for their neglect. They will reap as they have sown, and he will go to the bad under whatever system he is placed. Much of this outbreak of anxiety for the welfare of medical students is due to a still-existing delusion that the morals and conduct of medical students are worse than those of other young men. On this subject I will read you a passage from an address given to the students of this hospital thirty-six years ago by Sir Benjamin Brodie. After advising the students as to their conduct he said:—'Gentlemen, I offer you this advice, not because you are medical students, but because you are young men. I do not believe that you are more in need of such admonition than others of the same age. I know not what medical students may be at other schools, but as to those belonging to this school, with which I have been so long and so intimately connected, I feel it but just that I should express my sincere conviction that there was always as large a proportion of young men diligent in the pursuit of knowledge and decorous in their general conduct as is to be met with in any class of society.' That which Brodie said so many years ago I can now repeat; for if in these times of constant change we are in danger of losing some of our traditions, we still hold fast to that which is comprised in the motto, so brief and yet so comprehensive—'Manners make the man.' It is probable that, as the outcome of this discussion residences of some description capable of accommodating a few of the first-year's students will be established in connexion with some of the schools. Such an establishment would doubtless serve as an attractive advertisement and be a kind of harbour of refuge into which a parent might steer and anchor a troublesome youth, in the hope of finding for him there a more skilful pilot than he himself had proved. But that such establishments will ever be popular with students or have a beneficial influence on their moral training, or on their medical studies, I, for reasons already stated, have no belief. It is with students as with every living product of creation—a case of the survival of the fittest; and in the inevitable contest many of them will disappear.

My task is finished. I have spoken to you of subjects having only a passing interest. I might have addressed you from a higher standpoint, and told you of the endless potentialities of the science and art you are here to study—the science of life, the art by which that life is prolonged and preserved; that science has many problems to be solved and many secrets to be revealed; that art is yet in its infancy, and has many triumphs and rewards for those who shall carry it forward on its conquering course. They who have wrested the secrets of creation from the antediluvian rocks, or subdued the forces of the elements around us to the purposes of man, did not rest content with text-books or the words of the teacher. They went to them only to learn to read. They studied their real tasks with unceasing industry in the book of nature herself. Is less required from those who would read the mysteries of life? You learn here the alphabet and the primer. If you would go further and learn those deeper lessons which enable you to grapple with the enemies of life, with pain, disease, and death, you must read with your own eyes, you must reason with your own brains, you must feel with your own hearts, and your lives must be devoted to the profession into whose ranks you have this day entered as students."

KING'S COLLEGE

INTRODUCTORY LECTURE BY DR. GEORGE JOHNSON, F.R.S., EMERITUS PROFESSOR OF CLINICAL MEDICINE AT THE COLLEGE.

DR. JOHNSON began by referring to the death of Mr. H. Royes Bell, one of the most esteemed members of the surgical staff of the hospital, who, not long since, was suddenly called away, to the great grief of all who knew him. Then with reference to the three great subjects of anatomy, physiology, and chemistry, to which the student's attention has first to be directed, he said it need not be

Digitized by Google

insisted on that a knowledge of the structure and functions of the human body is an essential foundation for the practice of medicine and surgery. It may not appear so obvious, but it is not less true, that some knowledge of chemistry is absolutely necessary for every practitioner. In addition to its great practical utility, a diligent study of the facts and laws of chemistry will prove an invaluable means of mental training and discipline. Observation, memory, and the reasoning faculty are all exercised and strengthened by a thorough study of that delightful science. Referring next to the various classes of physicians, surgeons, general practitioners and specialists, the lecturer maintained that the only safe foundation for specialism is a thorough knowledge of disease in general, and he illustrated this by reference to diseases of the eye and the larynx. There are, he said, few, if any, special departments of practice which have so indisputable a *raison d'être* as ophthalmic surgery; but there are few diseases which afford so many and such striking illustrations of the close relationship between various tissues and organs and the dependence of apparently local structural changes upon remote, and often general, constitutional states as those which affect the eye. Thus, in one case, impaired vision may be seen to be caused by degeneration of the retina, the result of Bright's disease of the kidney; in another, blindness may result from mechanical obstruction of a retinal artery by a small blood-clot detached from a diseased valve of the heart; while in yet another, loss of sight may be due to degeneration of the nerve of vision, consequent on the growth of a tumour in the brain. Thus, an oculist unacquainted with diseases of the kidney and heart and brain would often fail to correctly interpret the ocular defects with which he had to deal; while on the other hand, a physician who undertakes the treatment of renal, or cardiac, or cerebral disease, without having acquired the power of inspecting the interior of the eye with the ophthalmoscope, is at manifest disadvantage. Again, the laryngoscope has shown that while in one case loss or impairment of voice may be due to some disease within the larynx, in another, it may be caused by an aneurysm or other tumour in the neck or within the chest pressing on a nerve which supplies the organ of voice; while, in yet another case, the laryngeal trouble is traceable to disease within the brain or spinal cord. A mere laryngoscopist then, whose vision is limited to the larynx, would be incompetent to deal successfully with the diseases of that organ. These and other like facts show that between the various organs and functions of the body there exists, both in health and in disease, a correlation, the recognition of which is of the highest practical importance. The universe is governed by all pervading immutable laws. As the astronomers, relying upon the laws of gravitation and of planetary motion, have discovered a previously unknown planet by observing the disturbed orbit of one previously known; as the biologist, in reliance upon the invariability of organic types, has been enabled from the fragment of a skeleton, or from a tooth, to reconstruct the framework of an extinct reptile or bird or mammal; so the pathologist and the practising physician, relying upon the laws of physiology, which, although modified, are not suspended by disease, have learnt that a disease commencing in one organ may involve widespread structural changes in many other parts. It is obvious, then, that the body cannot be separated into different parts so as to make one of them the exclusive object of study and practice. The lecturer entered a protest against the rapid multiplication of small special hospitals, which are injurious by diverting funds from the general hospitals, of which most of them are sorely in need, and by attracting special classes of patients which in the hospitals connected with medical schools would be utilised for the practical instruction of their students. Reference was made to the value of the various modern aids in the diagnosis of disease, such as the ophthalmoscope and the laryngoscope, and the importance of a correct interpretation of symptoms. A most important duty of the practitioner is to ascertain what in the habits or the surroundings of the patient is the cause of disease, and the frequent and powerful operation of mental influences was next adverted to. Referring to the disobedience of the law with regard to vaccination by a large proportion of the inhabitants of Leicester, Dr. Johnson said, "It is as certain as that the sun will rise to-morrow that at no distant period small-pox will invade the town of Leicester, and as a result there will be such a massacre of the innocents—innocent victims of parental ignorance and prejudice—as will probably carry conviction to that eccentric member of the House of Commons who lately had the assurance to ask for an inquiry into the practice of vaccination." Briefly referring to the question of medical ethics, the lecturer said that few special rules would be required if all could act upon the comprehensive maxim, "Thou shalt love thy neighbour as thyself." He warned his hearers against the error of supposing that their studies were at an end when they have obtained their legal qualification to practise. The conscientious practitioner must be a diligent student to the end of his days. The man who is too old to learn is too old to practise. "That which Lord Bacon has eloquently said of all knowledge is in an especial manner and degree applicable to the knowledge which it will be the chief business of your lives to acquire and to use for the benefit of mankind—'It is not a couch whereupon to rest a searching and restless spirit, or a terrace for a wandering and variable mind to walk up and down with a fair prospect, or a tower of state for a proud mind to raise itself upon, or a fort or commanding ground for strife and contention, or a shop for profit or sale, but a rich storehouse for the glory of the Creator and the relief of man's estate.'"

MIDDLESEX HOSPITAL.

INTRODUCTORY ADDRESS BY CECIL YATES BISS, M.A., M.D. CANTAB., M.R.C.P.,

ASSISTANT-PHYSICIAN TO THE MIDDLESEX HOSPITAL, AND THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

THE lecturer commenced by remarking on the object to be kept in view by one giving an introductory address, and then proceeded to offer a hearty welcome to the students present for the first time, and with whose aspirations, desires, and perhaps misgivings in view of the apparent difficulties before them, he strongly sympathised. "Let me," he said, "greet you as pupils and as fellow-students. Our office is to assist you to decipher the characters, written often legibly, often most illegibly, upon the leaves of that great volume of disease that this hospital constitutes; and as fellow-students we invite you to take your stand with us in its wards that we may study together the ever-new and ever-varying phenomena of disease, all sharing alike the conviction that the moment the consciousness of knowledge received shuts the eye to the access of more, the moment that the baneful idea of finality in such learning infects the mind, and we conclude that there is no more light or truth to break forth than that which we have perceived, that moment does the man who has finished his learning become unfit to be, in any worthy sense, the instructor of others. For in clinical teaching, as in all other training worthy of the name of education, according to the true meaning of that word, the office of the teacher is (and perhaps here more than anywhere) so to influence the mind of the pupil as to evoke and train his undeveloped powers for the independent observation and induction of the studied facts."

Having spoken of the increased strength imparted to the school by the addition to the teaching staff of Mr. Sutton and Mr. Hern, the lecturer referred to the advantage that would be derived by the students in the proposed residential college—"a building commodious and handsome, occupying the site of those adjoining edifices in whose windows many of you have had the opportunity, during your brief intervals of leisure, of studying domestic life in its apparel, utensils, and casual incidents." In congratulating the new comers on the choice of the medical profession, Dr. Biss said: "The ruthlessness of examining boards within, and the steady pressure of public opinion from without our borders, are forces that are steadily lifting the profession to a higher level of knowledge and skill, coupled with a greater delicacy of thought and work. And a force as strong as either of these is the improved tone of feeling within the profession itself as to the responsibility of its functions and the esteem they merit at the hands of society. The doctor was once expected to ring the servant's bell—in country houses, at least; nowadays, I fancy, the squire and the doctor would both feel equally ashamed to meet on such terms. Little wonder that it should have been so, when the art of healing was regarded as a mere craft rather than as an intellectual and scientific calling, demanding a mind expanded by education, trained to feel and decide for its patients in the direst emergencies of anxiety, pain, and danger. The barber, the leech, the apothecary, the surgeon of ancient days, a man dismal with bones and blood, formed an ascending series,

Digitized by Google

from which we now see evolved modern physicians and surgeons whose claim to a scientific recognition and a social standing equal to that of any other calling is, happily, justified by facts and, for the most part, admitted at the hands of society. Yet not altogether so: there is not yet that ability that there should be, even amongst educated people, to differentiate the physician from the quack and the surgeon from the bone-setter, and to discern that the advertising pretender or practitioner probably takes the course of displaying his merits to the world, not so much from fear that he might otherwise be unknown, as that if left to the prior recognition of more competent judges it might be decided that there was nothing worth publishing. Nor is the social recognition of our members yet all it should be, though, as to our rank and file, it is a simple statement of fact to say that the medical students and practitioners of modern times are, in point of general culture, knowledge, manners, and gentlemanly feeling, quite abreast of their fellows, who are aiming to fill, or who stand in, the ranks of the Army, Navy, Bar, and Church, while I venture to think that in point of earnestness for work, devotedness, and self-denial in it, they are second to none, and perhaps ahead of all." The lecturer then entered upon a survey of the path of study, and pointed out certain facts, which might, in the absence of personal experience, help his hearers to save time, concentrate their energies, methodise their work, and avoid the pitfalls into which many a student falls. He counselled them to practise from the first day of their course the thrift of time. The curriculum being limited to a minimum of four years, the division of the course of study had been framed so as to meet, stage by stage, the arrangements of the conjoint scheme of the Colleges of Physicians and Surgeons. It followed that no student had any time to lose. It was impossible for him who dawdled through his first year to make up satisfactorily for it in his second. When the second year came it would bring with it its own tale of work, and it was a real misfortune when a man found out too late the disadvantages of dislocating his work from its due relation to the curriculum, and had to grind away at revising for the anatomy and physiology examinations when he ought to have his mind at leisure for the clerkship or dresserships he had come to hold.

The lecturer went on to say that in medical study there was a special faculty that must be trained—namely, the faculty of close, shrewd, thoughtful observation, and the power of correct, inductive reasoning upon the phenomena observed, connecting effects with causes, and drawing true inferences. But that upon which he would ask his hearers to lay supreme emphasis was that in medical studies there was absolutely nothing that could supply the place of the observing faculty. With it all else might follow; without it a man could no more make a truly able physician and surgeon than an ordinary mortal could write Byron's poetry, fashion the sculpture of Praxiteles, or compose the immortal strains of Handel. Jenner observed, what indeed many had observed before, that cow-pox was communicable to man; but it was not till he had patiently carried out the toil of observation and induction for a very long time, and ascertained that it was only in a particular condition of the cow-pox pustule that the virus was capable of efficiently protecting the human constitution, that the magnificent discovery of vaccination was attained. "The noble words of Harvey, spoken two hundred years before, seems almost prophetic of his success: 'Nature herself is to be addressed; the paths she shows us are to be boldly trodden; for thus, and whilst we consult our proper senses, from inferior advancing to superior levels, shall we penetrate at length into the heart of her mystery.' ..... The demonstrative is the most interesting as well as effective method of instruction. Tell a child that heat expands mercury, and such-like facts, he yawns, or thinks of his marbles. Show him a thermometer, let him hold its bulb in warm water and see the index rise, and he is all interest; probably never will forget the fact; and, better still, will shortly apply the observing faculty, thus trained, to the attempted elucidation of something else. This is what makes medical study so charming: the method of demonstration pervades it. If your work is carried on on these lines, your progress will be sound, and you will really be trained, not for examinations merely, but for the more difficult work beyond. But if you substitute books for facts and words for things, you will find yourself in the end far wide of the mark, not having (as has been said) 'at the back of your mind, the change for words in definite images which can only be acquired through the operation of your observing faculties on the phenomena of nature.' I remember hearing one of my old teachers say—and it made a great impression on me—that the most clever clinical note he ever remembered to have heard read to him in the wards by a clinical clerk was found on examination of the patient to be incorrect—pure romance, not fact! Train your senses, then, by observing facts above everything, and you will be as much surprised at how little you can at first see, feel, and hear with certainty in handling cases of disease, as you will afterwards be at how much you can make out with perfect certainty when your training is advanced. ..... Let me venture to advise you to acquire your knowledge of anatomy from the structures themselves more than from books, though books, in their proper place, may not be neglected. Anatomy, however, can never be interesting if it be viewed as the aggregation of detailed facts. It is the grouping of those facts by relations of structure and function, and the generalisations that may be built upon such associations, that cause the subject to teem with interest and facilitate its comprehension. To notice such facts as that all the muscles which have for their function the expression of emotion are supplied by the facial nerve (though some of them in man are ordinarily insignificant and inert, such as the occipito-frontalis or the muscles attached to the auricle, yet in many animals largely subserving that function); or that, as was pointed out by the late Mr. Hilton, the same nerve that supplies a muscle or joint supplies the skin over the insertion of that muscle, or over that joint; or, again, that the nerves which supply muscles enter them at the points where they are the most secure from pressure, well illustrated by the curious fact that the phrenic nerves (literally 'the threads on which our lives hang') pierce the diaphragm, to be distributed upon its *under* surface, where gravitation tends to relieve them of the pressure of adjacent organs,—to note all this not only removes tedium from the work, but greatly assists the burdened memory by classifying in a natural manner the facts it has to carry to the examination table." Having warned his hearers against the danger of depending upon "tips" and "rhymes," the lecturer spoke of the place occupied by Physiology in medical studies. "Let me beg of you," he said, "to form a right conception of what that place is. Physiology is the science of *function*; it does not mean cutting and mounting sections or analysing fluids, important as these things are; that is but anatomy still, the minute anatomy of the tissue, or, if I may say so, of the fluid. It is when you ask, 'What does this muscle do?' 'What does that nerve connected with it do when contraction happens?' 'What is the chemistry of these changes?' 'What their relation to other vital processes?' and questions like to these, that you are studying true physiology. Much as our teaching has improved in this particular, it seems to me that there is room for improvement still. The precious hours of the physiology student are so much swallowed up by section cutting and staining (often so fascinating a thief of time) that the problems of pure physiology are but too little considered with that detailed reflection that they should be when it is remembered that so much of our future work in the treatment of disease depends upon the application of such knowledge. For let us never forget that there are many diseases that, in the anatomical sense, have no pathology. Epilepsy, migraine, diabetes, asthma, and not a few others, wait their complete elucidation at the gates of the medical physiologist. Grateful as I feel for the immense advances of physiology in recent years, and for the enormous advantages to medicine that the labours of such men as Michael Foster and Burdon Sanderson have conferred, I would with all deference venture to record the conviction that, advantageous though it be for some reasons, to study pure physiology—that is, physiology apart from its pathological bearings,—the day must come when the relations of pathological to normal function shall be more habitually studied together, and a fresher development of the science be reached, which, if less "pure" in its ideal, shall be much more complete in its scope, and much more useful to mankind ..... The examinations in anatomy and physiology over, the way is clear to clinical medicine and surgery for a space of two years. This is the period of supreme interest, as of supreme importance; utilise every moment of it. And that you may do so, allow me to offer you one or two counsels. Do not be

Digitized by Google

satisfied with the cases allotted to you, but study every case in your wards, and keep in your own case-book a concise record of each. Make a point of seeing every case, examining it (if there is no reason to the contrary), and forming at least a provisional diagnosis for yourself before the physician's or surgeon's visit, and, if possible, independently of the resident.....Remember, too, that it is the out-patient department, rather than the wards, that supplies you with the class of cases of the slighter disorders and accidents, as also of those functional, subacute, and chronic diseases that will form the staple of future practice, besides presenting to you a far greater number and variety of cases than the wards. The casualty department, too, must not be forgotten. There alone you will see the exanthematous and other rashes, sore throats, and cases of unusual character and sudden emergency, with special frequency and advantage."

The lecturer then offered the students some advice on the kind of books it would be best to read, and afterwards addressed himself to those who were drawing near to the end of their curriculum. "I may perhaps remind you, in the words of Sydenham, 'That the art of medicine is to be properly learnt only from its practice and exercise,' according to which definition your learning is now really about to commence. If, inspired by the philosophy as by the humility of this thought, you address yourself to the work before you, your success is certain—financially I trust, but, better than that, the success of real usefulness in life. Great responsibilities await you; but these are to be met by preparing for them, not by fearing them. And this preparation will be, and ought to be, a daily task: we must always be learning. Disease is no more stereotyped than are any other vital phenomena; and it speaks to us frequently, if I may say so in its *dialects*, which we must be as ready to understand as its ordinary speech. How needful, then, is it that we should carry forward the spirit of philosophical study with us through our daily round, and not degenerate into mere distributors of drugs—a work which the prescribing chemist or the quack can often do as well as we, finding, indeed, his *raison d'être* in our contentment with mere routine, a spirit which our patients too soon catch from us. 'You can always prescribe for him' I once heard advised to a student in a dilemma about the diagnosis, as a hint for his future practice. We may be very sure that it is of this spirit that is born the feeling in the public mind that blind empiricism is the best guide after all—a feeling the extent of which is witnessed by the endless columns of quackery in our daily papers." Alluding to the importance of the movement for the collective investigation of disease, Dr. Biss indicated three lines of inquiry, which, on account of their greater command of material, could be best worked out by men engaged in general practice—viz., (1) the varieties and relationships of the acute contagious disorders; (2) the real value and use of drugs in clinical treatment; (3) the complete examination and estimation of the value of family histories in relation to the etiology of disease. The lecturer concluded by exhorting his hearers to follow the example of the illustrious men whose names adorned the roll of *alumni* of the Middlesex Hospital Medical School.

UNIVERSITY COLLEGE.

INTRODUCTORY ADDRESS BY MR. A. E. BARKER, F.R.C.S., ASSISTANT PROFESSOR OF CLINICAL SURGERY AND TEACHER OF PRACTICAL SURGERY AT THE COLLEGE.

AFTER alluding to the tendency at the present day to disparage the custom of introductory lectures, the speaker pleaded for them that at least they afforded an opportunity of offering to newcomers launched for the first time on the wide sea of London life a hearty welcome on the part of their teachers, and the assurance that in all their difficulties they will have the sympathy of men who have trodden the same path before. If for no other reason than that these addresses helped to promote that personal cordial goodwill between teachers and students which ought to exist, and which is so apt to be tried, or actually to perish, in the hurry of the daily academical routine, they should be maintained and further developed. In University College especially, which gathered strangers from all parts of the civilised world, and where work is so absorbing, every means should be taken to assure all students that they were welcome. No opportunity should be omitted of drawing closer the social bonds between all its workers. Addresses of this kind might be made of use, too, in introducing students to some of the questions which must sooner or later present themselves to those entering the profession. In this case those present were asked to consider some of the relations of medicine to society and the State, and then to survey the position now accorded to the medical profession by the latter. Two questions were first propounded as bearing especially upon this subject. First, whether medical effort as a whole really resulted in actual benefit to the human race; and, secondly, whether the influence of the medical profession strengthened the moral sense of mankind or weakened it. In answer to these questions, the speaker alluded to what the public require to be constantly reminded of—namely, that their lives are daily protected and their happiness enormously increased by the discoveries of medical science as to the causation of disease as well as by the daily practice of the profession in relieving individual ailments. "The great laws of sanitation, embracing provisions for the prevention of epidemics and plagues, and the cleansing of cities in the wisest and most economical manner, the regulations regarding the examination of food with a view to the prevention of adulteration, and to secure its purity, all owe their inception and much of their elaboration to medical science." The remarkable reduction of the death-rate in large towns within recent years was pointed to as one practical outcome of all this. The immense diminution of suffering and death owing to the discovery of the causes of mortality after wounds and the introduction of the antiseptic methods into surgery were alluded to as special illustrations of the good reaped from medical effort. As to the question whether the moral sense of mankind is strengthened and elevated by scientific medical thought, it was pointed out that the profession is assailed by two different sets of thinkers from two opposite sides. One set asserts that the tendency of our teaching in physiology, biology, &c., is directly towards pure materialism, the other charge us with sacrificing strict reason and yielding in our life work solely to humanitarian sentimentalism and religious enthusiasm. The first reproach us with undermining old and revered beliefs, the second taunt us with committing inconsistencies and blunders, such as prolonging or saving lives rendered miserable by disease we are at present powerless to cure. Referring to these charges, the students were assured that neither is well founded, that the medical profession of all others is least open to the taunt of being carried on in defiance of reason, its whole work having a scientific basis; and that the sadder reproach of arid materialism is equally baseless in view of the spirit of lofty devotion to the older, grander principles of pure charity exhibited daily in the whole work of the profession. As to the charge of undermining the venerable and cherished beliefs of mankind, a few illustrations were furnished from medical teaching showing how some of their best doctrines are confirmed and rendered more intelligible thereby. As students then in this calling, beneficial alike to the bodies of men and to their moral being, the audience was invited to consider how far society and the State accorded that position to the medical profession which was its due, and what both were doing to further stimulate its beneficent energy. It was pleaded that society treated medicine with comparative coldness, that the fact that medicine was rapidly developing into a public service was not recognised, that the State encouraged it but little in comparison to other professions with no higher aims or practice. It was pointed out that while public thanks and public funds were often voted in Parliament to successful commanders and diplomatists, nothing equivalent was forthcoming for the great discoverers in medical science, whose work affected the lives and happiness of millions for all time. Even the less substantial though prouder honours of high position near the throne and hereditary titles were rarely or ever bestowed on medical men. It was suggested that the State might itself derive much benefit by the more public recognition of its achievements and by grants for the prosecution of further research, as well as by calling the highest minds of our profession into its councils officially. It was also suggested that the gracious Sovereign now on the throne, who has ever shown such a warm sympathy with all that ministers to the happiness and improvement of her people, might greatly encourage the medical profession by calling some of its leaders nearer to the throne and giving them a place on her Privy Council, or even among her peers. The result, it was contended, would be beneficial to the Upper House in

Digitized by Google

many ways, and would also benefit the nation when certain questions of legislation came to be discussed there. It was also thought by the speaker that the interest already occasionally shown by members of the Royal Family in the greater meetings of medical men, if more frequently exhibited, and especially in the annual gatherings of medical students, might stimulate the public to sympathise more with medical life a matter in which the whole nation is very deeply interested. The same personal interest that is shown by our Royal Princes in the doings of the army, the legal, and even in the musical and other artistic professions would not be thrown away if bestowed upon medicine. But while these things were put forward as worthy of the attention of society, of the State, and of the Crown, the prospect of their being granted was not held up as an inducement to younger men to enter the medical profession, and to devote themselves to it. The divine science and art of healing contained in itself the highest of all rewards worth seeking. It offered to the highest intellects problems which should carry them into the deepest mines of research or up to the loftiest regions of speculation. It offered also to men of warm sympathies quiet walks in the valley below amid the homes of men, where they would have the freest outlet for all their purest impulses, the widest field for kindly, patient, useful activity for others. It offered, in short, to all earnest men work of the best kind suitable to their particular bent, and if old Carlyle's saying is true, that "blessed is the man who has found his work, let him ask no other blessedness," Medicine has indeed the highest reward for all her sons.

WESTMINSTER HOSPITAL.

INTRODUCTORY ADDRESS BY MR. JAMES BLACK.

THE introductory address was delivered by Mr. James Black, B.A., F.R.C.S., lecturer on anatomy at the new schools in Caxton-street, Westminster, on Oct. 4th, at 3.30 P.M. He stated that he thought the time placed at his disposal would be most profitably employed in offering a few words of practical advice to those who were commencing study for the medical profession, and some suggestions relative to preliminary training and future prospects. One of the first questions arising was how the student should profitably employ his time. The answer to an extent was furnished in the prospectus, where he would discover that most of the hours of the day were mapped out either for attendance at lectures and demonstrations, or for practical work in the dissecting room and chemical and physiological laboratories. Students, however, quickly discover that, even then, their labours are not at an end; but that extra hours must be spent in reading over those subjects which had occupied the mind during the day, and which would be quickly forgotten unless subjected to methodical and critical reflection. The inquiry also arose, should there be no time for recreation and out-door exercise? The reply was undoubtedly there should be, for a curriculum defective therein must inevitably produce pernicious results. From his experience at Cambridge the lecturer advised that a moderate indulgence in athletic sports was well calculated to develop the student's physique as well as cultivate his mind. He complimented the school on the fair success which had attended their efforts in the public competitions, and referred particularly to the case of one gentleman who upheld the credit of their hospital in the sports, also carried off the exhibition, scholarship, most of the prizes, and, what would prove of the greatest value of all to him, was in turn elected to several valuable appointments in the hospital. Concluding his remarks on this subject, with the caution that such devotion must be circumscribed within due limits, Mr. Black spoke a few words on music and drawing, which he strongly advised his hearers to cultivate. Music was a special blessing; it afforded the most perfect solace to the jaded intellect. As Dr. Clouston, in his address on Psychology before the British Medical Association at Brighton, explained, "Intense thought will inhibit emotion; whilst, on the other hand, intense attention to objective sounds will inhibit thought." The medical profession included within its ranks many who, to judge by the excellence of their art work, had reached the pinnacle of fame as artists, and who, none the less, had attained an exalted position in their own profession. Dr. Oliver Wendell Holmes, whose recent visit had reminded us that literature too, has for one of its brightest ornaments a member of our profession, happily remarked—"Literature is a good staff to walk with, but not a good one to lean upon. Coleridge had told him, 'Every man should have as well some fixed and regular occupation,' and this advice he would hand on to any who might feel tempted to exchange the steady preparations for a practical career for the uncertain pathway of a literary life." Edward Jenner, one of the greatest benefactors of mankind, often solaced himself, when the cares connected with the progress of his discovery weighed upon him, by playing on the violin and flute with all the mirth of youth. Whilst, then, avoiding unmitigated study, the student should vehemently despise the wanton recklessness of uninterrupted frivolity. To those who could not help working, even at the expense of their bodily and mental powers, he would say, Guard against this as much as possible by systematically taking a good night's rest and sacredly observing the Sabbath.

To proceed to the course of studies, the field open to the medical student was endless in variety, as was illustrated by reference to the following, among other subjects: anatomy, physiology, and chemistry. Allusion was made to the researches of Fraser, Crum-Brown, Lauder Brunton, and others, who have established a scientific explanation of the action of different substances founded on the investigation of their molecular constitution; a distinct connexion being proved to exist between the specific atomic grouping of these bodies and their physiological action. And Mr. Cresswell Hewett's remarkable discovery of the synthetical manufacture of quinine, by which the price of the drug was likely to be reduced to something like 3*d.* per ounce, was also referred to. A certain amount of natural science, physical and biological, the lecturer thought, should be acquired before joining a hospital school, and he sketched out a preliminary course founded on the lines lately laid down by a committee of naval instruction for the preliminary training for the navy. At fifteen an examination equivalent to that for the lower certificates conducted by the Oxford and Cambridge School Examination Board was to be passed. For the ensuing year the boy should remain at his school and specially devote himself to mathematics, physics, modern languages, and drawing. At sixteen, when the above committee decided the naval cadets should join the *Britannia* training-ship to pursue a year's course of technical and nautical instruction preliminary to the succeeding three years spent afloat, when, of course, their studies would be strictly practical and professional. Mr. Black proposed that the candidate for the medical profession should attend some well-equipped laboratory for the ensuing twelvemonth, where he was to be practically taught biology, chemistry, and physics. Certificates should be required of having undergone such a preliminary training, and the student be expected to matriculate in the above subjects on entering a hospital school. The lecturer, whilst profoundly appreciating the value of a thorough classical education, could not but feel convinced that by adopting some such course as the above there would be more likelihood of the student successfully completing his present curriculum in the allotted four years, and that the benefit of a satisfactory preliminary scientific training would become universal, whereas such is now too much limited to those only who intend taking a university degree. Referring to future prospects, he congratulated his audience on the chance there seemed of taking an M.D. degree in London on the same conditions that already existed at certain universities. The corporation of the venerable College of Physicians and the illustrious College of Surgeons amply provided England with a truly representative body, admirably suited to confer an M.D. degree on all really well-educated metropolitan students.

In conclusion, Mr. Black observed that the success of their own school depended mainly on themselves—not less upon the students than those who were members of its staff. All must be actuated by high motives. The splendid site of the hospital, under the shadow of that Abbey where lie the ashes of the good and great, the long roll of eminent men who devoted their services to the good work done in the hospital, and, lastly, the enormous vitality which had enabled the school to survive the crushing blows it had received during its existence of half a century, and to appear as it now did, must inevitably inspire them all with enthusiasm to do their utmost to maintain the traditions of the past.

ROYAL VETERINARY COLLEGE.

IN his introductory address Professor ROBERTSON referred to the changes which had taken place in our views of matters purely biological and pathological. In both human and veterinary medicine, he remarked, the elaboration of the germ theory of Pasteur in its earlier triumphs in the department of surgery is likely to be surpassed by what we may reasonably expect will yet be achieved in the domain of medicine. In preventive medicine, as applied to animals, the recognition of the specificity of many of those diseases which have attracted attention through their destructiveness has given us a solidity of basis in dealing with them which was unattainable while they continued to be regarded as the result of variable influences, sanitary and dietetic. Professor Robertson afterwards directed the attention of his audience to the arrangement of the students' curriculum in its two great divisions of theory and practice, exhibiting the relation of one to the other, and pointed out that no facilities, however abundant, nor teachers, however good, would of themselves be sufficient to enable anyone to secure the ends contemplated unless they were supplemented on the pupil's part by earnest work and the exercise of observation and reflection upon all the facts, physiological and pathological, which they encountered.

SHEFFIELD SCHOOL OF MEDICINE.

INTRODUCTORY ADDRESS BY DR. WILLIAM S. PORTER, LECTURER ON PHYSIOLOGY TO THE SHEFFIELD SCHOOL OF MEDICINE, AND PHYSICIAN TO THE SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.

DR. PORTER, after defending the retention of an introductory lecture and welcoming the new students, said that they had chosen a profession which only offers very limited rewards in a worldly sense, which would make great demands upon their powers of physical and mental endurance, which would impose upon them duties and responsibilities requiring the exercise of much delicacy, tact, and discretion; and which might expose them to personal danger, and their reputation, and even liberty, to some risk. What, then, is there to counterbalance these disadvantages? Pecuniarily, an honourable competence, if nothing more, the medical profession does offer with tolerable certainty; intellectually, a wider and more interesting field for study than almost any other vocation; and, if pursued conscientiously and faithfully, the esteem and gratitude of many of their clients and the reward of an approving conscience. In the words of one who has left us for all time the memory of an honourable and upright life, and the classical productions of his pen, the late Sir Thomas Watson: "It affords ample scope and exercise for the intellect, and is conversant with objects that tend to elevate the thoughts, to chasten the feelings, and to touch the heart." Although it may be undertaken from no higher motive than that of earning an honest livelihood, it is a profession which affords greater scope than most other vocations for the exercise of philanthropy; and it is in availing ourselves of the opportunities afforded us of doing good and unselfish work that we can establish its claim to the attribute of nobility, with which on these occasions it is customary to invest it. It is in the sacrifice of our own comfort, and even safety when necessary, in the interests of those committed to our care; in the little acts of kindness, forbearance, and consideration to those who have, perhaps, only their gratitude to offer in return, that the higher ideal of our vocation is realised. He was not one of those who see very much to grumble at in the social status and position which are accorded us as a profession. We are not a wealthy body, and cannot expect to compete with the advantages which wealth confers; and in this respect we rank much as other professional men do. As individuals, general culture, education, and some advantages derived from early associations and training will always obtain recognition; and the position which a man's individual qualities win for him is more satisfactory than one which is accorded him in right of his profession. If he is a gentleman, and shows that he is actuated by gentlemanly instinct in his private and professional relations with others, he needs no table of precedence to maintain his rank, and is above the disparagement of vulgar minds. But as it is that which cometh out of the man that defileth him, so is it the acts of members of the medical profession themselves that lower their vocation in the eyes of the public. Let it be the aim of each one to maintain the traditions and honour of the profession in his relations to the public, to his patients, and to his medical brethren; that when his race is run he may hand on that honourable heritage to his successors with the knowledge that it has never been disgraced by any act of his. After briefly sketching the curriculum and advising his hearers as to their studies, Dr. Porter entered into a long and eloquent defence of vivisection, and, alluding to Ferrier, Pasteur, and other workers, pointed out the benefits which the world has reaped from their investigations, which could not have been carried out without experiments on animals. "More recently," said the lecturer, "Professor Ferrier and others have made most important discoveries in connexion with the localisation of function in the brain by experiments upon animals. These experiments have not only furnished us with the means of diagnosing, in some cases, the exact situation of a tumour or other local lesion in the brain, but they have also demonstrated the fact that such lesions are within the reach of operative surgery." The concluding words of the address were as follows:—

"Gentlemen, there is a great future before us as a profession, a future which is already beginning to take very definite shape. Great social and physiological questions are casting their shadows before them, and the public are learning to look to us for advice upon matters which concern the health and prosperity of the nation as well as the single interests of the individual. Public health is yet an infant science; let me urge upon you all the importance of its study. The prevention of disease, although it may be the means of cutting down our own incomes, claims a natural precedence over the curative department of our art. One of the social problems of the day is what is known as the alcohol question. And it is not merely the effects of alcoholic excess upon the individual, but the effects transmitted to the race by heredity that brings this question within the domain of public medicine. We have long been familiar with the degenerative lesions in tissues and organs and their consequences produced by long-continued and excessive indulgence in alcohol; but we are only beginning to realise fully, in connexion with this question, by the study of mental disease and brain pathology, the awful fulfilment of the threat that the sins of the fathers should be visited upon the children. We know now how this tendency to degenerative change in the delicate tissue of the brain may be handed down from generation to generation, unless corrected by other hereditary influences and healthier modes of life; and how much mental and moral instability, as well as actual insanity, may be assigned to such a heritage..... In the course of your clinical studies regard alcohol in the light of a drug, often an invaluable one, and notice particularly in what sort of cases and for what conditions it is prescribed, that you may apportion it its proper therapeutic value, and not use it recklessly or indiscriminately. We, as a profession, have often been charged with fostering a passion for alcohol by ordering it indiscriminately; but I believe that such charges generally come from those who seek to excuse their own weakness and want of self-control. Be especially careful how you prescribe it in the case of children and young persons, or for those in whom there is reason to suspect an inclination to indulgence in alcohol, opium, or chloral, for the craving for any of these is an indication of the same essential condition of brain. In treating those who are addicted to alcoholic excess the employment of moral therapeutics is mostly called for, and may not we as medical men do something in this direction? Let us at least endeavour to ward off temptation from those in whom we have reason to suspect an hereditary tendency. Here it is that teetotal organisations come to our aid, and we cannot too gratefully acknowledge their help as a means of voluntary restraint under such circumstances. With those upon whom this vice has fastened we have much less hope of success; but the only course to pursue, I believe, is to insist upon as complete abstinence as possible. I have heard the objection urged, that if you do so your patient will probably leave you and go to somebody else, who is, perhaps, less conscientious and more indulgent to his weakness. Well, gentlemen, I think it is a question of your duty to your patient to advise him for the best; and the fact that others may not be so scrupulous does not absolve you from the obligation to do your duty at whatever cost. Your studies may, not unnaturally, lead you to reflect upon the relations

Digitized by Google

of theology to scientific teaching. The progress of science has led some of its most distinguished votaries to seek in natural laws the explanation of all that has been hitherto regarded as evidence of supernatural existence, and to refuse credence to anything which is insusceptible of proof. There is in the human mind a natural desire to probe everything to the bottom, and a yearning after finality which tempts us to hasty inferences and conclusions. There are epidemics of opinion as there are epidemics of disease, and the world's history shows us many such instances of waves of infidelity and doubt. The deeper scientific investigation penetrates the more the unity of nature is becoming apparent. In the words of Sir James Paget, 'As the rays of knowledge have extended and diverged, so has their relation to one common centre become more evident, and the unity of nature has become more significant of the unity of God.' Let us rather hold by our faith, and wait in patient confidence for the light of further knowledge. If we renounce our faith, what have we left to live for?

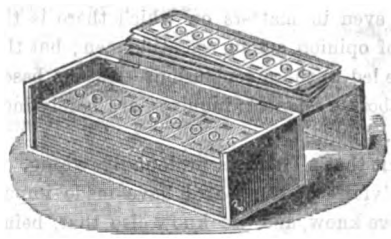
'Work without hope draws nectar in a sieve,
And hope without an object cannot live.'

The spread of materialism warns us that we are in danger of drifting into the realisation of Pope's prophecy in the closing lines of the 'Dunciad':

'Lo! thy dread empire, Chaos! is restored,
Light dies before thy uncreating word.
Thy hand, great Anarch! lets the curtain fall;
And universal darkness buries all.'"

UNIVERSITY COLLEGE, LIVERPOOL.

PROFESSOR CONWAY, in delivering the introductory address on "The Succession of Ideals," said the spiritual and intellectual products of the human mind are different at different times and in different places. It is with humanity as with individuals. No one is the same at any two moments. What a man strives and hopes, and even lies and sins for at one time, may be unattractive, may be hateful, to him at another. No conception returns unmodified to the mind. Do what he will, his work repeated results in something new. The ideals of youth, of middle life, and of age, how they differ one from another—differ as widely as the ideals of different men. As with the individual, so with the nation, with the race, and the sum of the races. That which mankind as a whole, or which nations as a whole, have at any time striven after, in so far as they have attained it, enters into the sum of human possession, and may become the property of the individual; nay, if it has once produced a moulding effect upon the race, heredity stamps the sign of it on the babe unborn. Any study, if pursued to the end, leads on to all other studies. Any fact may be chosen as the centre of all knowledge, because whilst the area of what is known is limited, the universe or possible knowledge is infinite. But the boundaries of the known are constantly enlarged, first in one direction, then in another, by the passionate striving of men outwards. The goal-point of one generation's endeavour becomes a detail in the possession of the next. The centre of effort changes, but that which has been a centre ceases not to exist, because the forces of humanity bear past it instead of upon it. A fact does not become more true by being known, nor an ideal more fine because men strive towards it. Whatever part of any ideal is true and good remains for ever a possession of mankind. Every ideal worthy of the name manages to get itself enshrined in some form that would endure if only men cared to preserve their heritage from the past. He that destroys a thing that another once laboured to make murders a dead man. An honest carpenter may continue the influence of his honesty long after his death, if the work he had done be respected by those privileged to use it. If they wilfully destroy it, the good man's influence is at an end. The work of the dishonest clears itself speedily enough away. We may destroy what we please, and leave behind whatever wilderness seems to us good to be our record in the face of eternity. The noble works of noble men once formed we may demolish, and so make the desert about us more complete. Their noble deeds once done we may forget; but works and deeds are beyond our power to annihilate; they have a larger and higher existence there where the hand of man reaches no more back to wither and destroy. Dreaming of such an existence, and of such only, is it possible to say to any man, or race, or civilisation, or ideal, *esto perpetua?*



LEEDS SCHOOL OF MEDICINE.

THE REV. F. J. JAYNE, vicar of Leeds, said that whilst trying to find and think out some appropriate topic for this introductory address, he was at the outset impressed by the very large amount of ground common to the various departments of education and the different professions. What is true of one is found to be true, with a few obvious modifications, of all. The physician must possess certain mental and moral qualities—promptitude, discernment, firmness, and the tact which can bring men and circumstances to contribute towards the end he has in view. The learning of the specialist may be profound, his enthusiasm pure and ardent, his instruments and appliances the best that money and contrivance can procure, yet if he lacks the practical wisdom which will enable him clearly to read and deftly to handle those with whom he has to do, he will be baffled and daunted by difficulties of no real moment, he will cause confusion where he should have established confidence and order; he will fail where others, in some respects his inferiors, would have achieved a conspicuous and solid success. We must not be content with a commonplace and low-pitched estimate of the end towards which we are moving. In the very childhood of the medical art a clear and lofty conception of its functions and responsibilities was formed and established. Having briefly sketched these responsibilities, Mr. Jayne impressed upon his hearers the importance of cultivating those moral and spiritual qualities in the absence of which our opinions may, indeed, have the subtlety and brilliancy of the advocate, but not the impartiality and authority of the judge.

New Inventions.

NEW PORTABLE CABINET FOR MICROSCOPIC SLIDES.

MR. MEDLAND, of the Borough, London-bridge, has forwarded for our inspection a specimen of his new portable cabinet for microscopic objects. Its chief recommendation is the circumstance that without greatly increasing the size of the ordinary cabinet (which can accommodate six dozen

slides), the new box can enclose, without more than the usual risk, twice that number. Each glass slide is secured in its place by part of a long flap that projects for a quarter of an inch or so over each end of the oblong slide. This arrangement may with advantage be made more efficient by means of slips of elastic ribbon, which should cause the flaps to snap back after any desired slide had been removed. The price of the cabinet, which is cased in polished pine, is 7*s.* 6*d.*

POISON GUARD.

MESSRS. PITTUCK and SNOWDON, of Hebburn-on-Tyne, have recently patented an appliance which is intended to prevent the accidental handling and unintentional dispensing of poisons. The apparatus, if such a simple, though withal effectual, contrivance merits a name of such dignity, consists of a brass collar to be fitted to the bottle neck, and a perpendicular slide consisting of two bars, which pass, one on each side of the handle of the stopper, and so keep the stopper base firm in the neck of the bottle. When this fastener is used, the immunity from error through unwittingly dispensing poisons from ignorance or absent-mindedness is complete. No one can remove the stopper from a bottle to which this guard is fitted except by a deliberate act requiring the use of both hands. Druggists and medical men who dispense their own medicines would do well to protect their poison bottles by means of this guard.

THE LANCET.

LONDON: SATURDAY, OCTOBER 9, 1886.

THE recently published annual report of the Metropolitan Board of Works illustrates at once the strength and the weakness of the great London sanitary authority. The work entrusted to the Board by scores of Acts of Parliament is enormous both in extent and magnitude, and all agree that a great part of the work is done well. Theoretically Parliament has, of course, control over the Board, but none is in practice exercised, and for more than thirty years every successive Act has increased the powers of the metropolitan authority. Questions are occasionally asked in the House, but the usual official replies are always forthcoming. Either the Board "will make the necessary inquiries," or "it has the matter under consideration," and neither Parliament nor the country takes any further trouble. The apparent indifference of the public to the proceedings of the Board in matters of vital moment is indeed remarkable. It is based, we venture to think, less on unlimited trust than on imperfect knowledge, and a conviction, founded on experience, that interference would be useless. The annual report affords abundant evidence in support of this view. It is absurdly meagre considering its immense range, and the evidence given in support of its statements is often most vague. Frequently, indeed, no evidence of any kind is adduced. The conclusions to which the Board in its wisdom has arrived are stated in few words and with ample self-confidence, even in matters on which there is the widest difference of opinion among scientific men; but the reasons which have led to those conclusions—reasons based, we are told, on elaborate scientific inquiry—are barely indicated in few lines.

We submit that all this is profoundly wrong. That the scientific advisers of the Board have made important experiments we know, and we know also that, being men of great skill and high repute, their experiments are valuable contributions to sanitary science. Whether other sanitarians agreed or disagreed with the inferences, they could not fail to be benefited by a study of the researches. Why, then, are these researches withheld, and with them the written opinions of the eminent scientific authorities who have been consulted? The Board arrogates to itself the position of a private company trading with its own capital, whereas all the world knows that its money is public money expended in enormous sums by a public department. Whatever scientific evidence is gained by the expenditure is public property, and should be available, not only to Londoners, but to the whole civilised world. There is another assumption even worse than this in the position taken by the Board. It assumes the right to wage war against those who on scientific grounds venture to differ from it, as though they were guilty of heresy. And the war is not waged fairly; for the arguments of the opponents are not duly set forth, and are only met by dogmas based on evidence alleged but not stated. The defendant in a civil action would scarcely be justified in adopting such a course, and it is palpably absurd in a body created by the Legislature and supported by the money of the ratepayers. If the policy of the Board be right, why object to showing the grounds on which it is based? If it be wrong, who will be damaged by its modification?

These criticisms apply to many parts of the report before us, but above all to the two or three scanty pages which are entitled "The Sewage and the River Thames." This exceedingly important question was, as our readers are well aware, forced upon the attention of the Metropolitan Board of Works by the reports of the Royal Commission on Metropolitan Sewage Discharge, which was presided over by Lord BRAMWELL. This Commission, in two reports—the second even stronger than the first,—condemned the system of river pollution which the Board devised, and which during the sitting of the Commission it defended with elaborate evidence and at enormous expense. The Commissioners, among whom were three distinguished chemists, two of them physicians, decided against the Board after a most protracted inquiry, and advised in the most forcible terms that the sewage of London, which polluted the Thames throughout the whole tidal area, should be carried down to a suitable spot in Sea Reach, there *purified*—the italics are important,—and afterwards thrown as a clear effluent into what would practically be an arm of the sea. Parliament is, most unfortunately, for the present, unable to deal with great social questions such as this when they involve matters of controversy. Ireland and Egypt, not to speak of Bulgaria and Burmah, make it impossible to do anything for London, and so the matter was referred to the Metropolitan Board of Works, although that body had spent an enormous sum in opposing the conclusions finally adopted unanimously by the Royal Commissioners. What the Board has subsequently done is about what might have been expected. It is set forth with almost contemptuous curtness in the present report. One point is, indeed, conceded in face of the overwhelming testimony adduced before the Commission. It is no longer pretended that the pouring the sewage of all London in a raw state into the Thames near Woolwich is no injury or danger to the river. Many witnesses, indeed, asserted as much before the Commissioners; but the Commissioners themselves inspected the river, and as several of them were half poisoned by the stench, and recorded the fact, the contention had to be abandoned. The first line of defence was, after hard fighting, found to be untenable, but another as near as possible to the old was at once adopted, and there in its new ditch the Board at present remains entrenched with a new show of obstinate valour.

This second line may be shortly described as follows. The present outfalls are to be retained. Barking and Crossness, and the New West Kent outfall opposite Purfleet, are, it seems, essential, in spite of the very strong opinion of the Commissioners to the contrary. But in a leisurely manner "purification" is to be adopted at each outfall. Some portion of the solid matters is to be precipitated with sulphate of iron and lime. After settling for "an hour or two" the effluent is to be thrown into the river. The first idea evidently was to throw it in without further treatment, but as, in the opinion of the chemists consulted, "in hot weather something more would

Digitized by Google

be necessary to ensure complete immunity from offensive effluvia arising from secondary fermentation"—in other words from putrefaction,—it was decided to treat the effluent with permanganic acid (that is, with a mixture of manganate of soda and sulphuric acid) before sending it into the river. As to the sludge, of which even after pressing there would be 850 tons daily, the Board properly despairs of disposing of it in the vicinity of the outfalls. It therefore proposes to purchase steamers of suitable construction, which shall carry the objectionable deposit out to sea; to what part of the sea we are not told. Then follows in the report a passage of almost child-like simplicity in regard to the alternative scheme of carrying the sewage further down the river. This scheme was submitted to the Commissioners by Sir JOSEPH BAZALGETTE, the engineer to the Board, who, by-the-bye, on a previous occasion had declared it to be impossible. It involves, of course, more expense than the present dirty system, even with its proposed modifications, but the expense would be a small matter for London, and it was strongly and unanimously recommended, as far as its main features go, by the Royal Commissioners, among whom were some very eminent engineers. It is dismissed by the Board in a few lines. The Board objects partly on the ground of expense, but mainly, as we gather, because Southend objects. Surely the force of absurdity could no further go. The Board maintains, first, that the sewage of all London thrown raw into the river near Woolwich does not damage the river; secondly, that any possible sentimental objection may be removed by purification at the outfalls; and thirdly, that the discharge of sewage in Sea Reach would be an irreparable injury to Southend. The Board calmly ignores the condition insisted on by the Royal Commissioners, that even at Sea Reach the sewage ought to be disinfected before entering the river. In Canvey Island, or near it, both the sludge and the effluent could be effectually, economically, and conveniently applied to the land.

OUR readers will learn from letters we publish elsewhere that the committee formed to promote the election of Dr. GLOVER to the Medical Council has been asked to join what is now known as the Birmingham Committee, who resolved last week to adopt as their candidates Mr. WHEELHOUSE, Sir B. W. FOSTER, and Dr. GLOVER. After due consideration this invitation has not been accepted, and the two committees remain separate, each to pursue its own particular aims. The reasons alleged by Dr. GLOVER'S committee for this decision are in our opinion conclusive. Some of his supporters are already pledged to other candidates, while many others "decline to have their freedom of selection curtailed." It is this latter point which must be steadily kept in view. Unless the general body of the profession determines resolutely that it will not brook any limitation of the most perfect freedom of selection of its representatives, there is a great danger that the gift of direct representation will become worthless. For years we have been suffering the disadvantage of having a Council composed of men chosen in a very large proportion by the governing bodies of medical corporations and universities. Matters will not be mended if to them are added other men selected by a small self-appointed committee, and who will be able to pose as the representatives of the thousands in the ranks of general practice. All registered practitioners must be careful to exercise their new right independently, and not submit to the dictation of a committee which assumes to itself the power or the right of selecting the most eligible candidates. We believe that the feeling in favour of a perfect freedom of selection is very strong, and that if this feeling is tampered with a storm of remonstrance will be evoked from the constituents. By all means let us have candidates recommended as suitable for posts on the Council by committees of their friends and acquaintances; but this having been done, let the selection of the three who are to represent the practitioners of England be left absolutely free and unfettered.

Of the merits and claims of individual candidates, it is perhaps not the time to write fully. We would deprecate an early pledging of votes. Better is it for an elector, when canvassed, only to promise to consider well the claims of the candidate in question, and then to vote only for those who will most surely express at the Council the views of the great electorate. An intimate acquaintance with the duties and responsibilities of general practitioners is a prime requisite in a good candidate. A knowledge of the past work of the Medical Council, of its duties, its powers, its resources, and its defects, is scarcely less valuable. A desire to advance the highest welfare of the profession and to free it from all that savours of charlatanism and chicanery is also important. Mere professional eminence and merit, praiseworthy as they are, will not—must not—be accepted in lieu of these requirements.

AT the recent Congress of the Sanitary Institute Dr. SEATON read a paper on the Notification of Infectious Diseases, as to which he had, in his former capacity of medical officer of health for the borough of Nottingham, a somewhat wide experience. He takes it for granted that, both on the part of the medical profession and on that of the public generally, the need for notification is generally admitted, and in this view he is doubtless correct. But the progress which is being made in the extension of the system is slow, and this tardiness is due to a number of difficulties with which the subject is surrounded.

In the first place, the actual utility of compulsory notification in preventing the spread of infectious diseases is, in several respects, not so marked as had been anticipated. Where such diseases as cholera and small-pox are concerned, there is, except perhaps as regards the latter disease in the metropolis and some large cities, little difficulty in securing notification and in dealing with the sick; but when scarlet fever, the most fatal perhaps of our current infectious fevers, is in question, it is extremely difficult to show that, apart from such general diminution as has during the past few years prevailed throughout the country, any material result has followed in the towns where the system of notification is in operation. Such result as has been obtained relates rather to a diminution in the percentage of deaths to attacks than to any falling off in the number of cases. It must, however, be remembered that the system of notification has not very long been in operation, and that the time which has elapsed may scarcely have sufficed to have allowed of any material

Digitized by Google

effect on an infection which has acquired the firmest possible hold on the inhabitants of our towns. Then, again, such failure as has followed on compulsory notification must, to an important extent, be set down to the want in many districts of any efficient sanitary organisation for dealing with the diseases notified. There are, indeed, towns which have made little or no use of the special powers granted to them, and which have not so much as a decent hospital for the proper isolation of first attacks of such infectious fevers as constantly occur in their midst. Neglect of this sort tends largely to bring the whole system into serious disrepute, and although we do not doubt that some good may be done by way of controlling school attendances and otherwise, where notification is not followed by any efficient isolation and disinfection, yet we are inclined to think that in the long run it would be advantageous if powers of compulsory notification were withheld from all authorities until they had shown their intention to make proper use of the information they wished to acquire, by providing an appropriate hospital and some efficient means of disinfection.

The difficulty of deciding who is to give the notification to the sanitary authority must also be regarded as a prime obstacle to any rapid extension of the system. Dr. SEATON, as an officer of health, evidently feels very strongly that the medical practitioner in attendance on the case is the proper person to make the notification, and he instances the case of Greenock, where notification has had to be made by the householder, as typical of the failure of the latter method. A perusal of the current reports of medical officers of health favours the same conclusion, and in the towns where notification is required both of the householder and the medical man, it is admitted that the former is rarely or never required to make it, and that it is almost invariably effected by the latter. But at the same time it must be remembered that there is a strong feeling on the part of a large number of medical practitioners that this duty should not be imposed upon them by the Legislature, and until they can view the matter in the same light as the medical officer of health does there will probably be no very large extension of the system. But notwithstanding all the drawbacks which attach to the compulsory notification of infectious diseases, as now carried out, it is certain that for the class of disease of which enteric fever is the type much good has been done, and more still is in progress.

The inspection of premises which follows on the notification of such diseases has revealed a large number of defective sanitary conditions which would otherwise never have been discovered, and the action which has been taken to secure their abatement has greatly tended to an improvement of the circumstances under which the people are living in the sanitary districts where exceptional powers as to notification are in operation. Works of water-supply, sewerage, and of house drainage, the prevention of overcrowding, the control of dairies and the sale of milk, have all been materially facilitated by the discovery of infectious diseases under conditions which have called for action on the part of the sanitary authority; and even if this were the only result as yet attained by notification, it would be an important one. But the time has not yet come when it can be shown that all the results originally claimed for the system have been brought about.

There is one part of Dr. SEATON'S paper with which we cannot agree. In dealing with the question of providing means of isolation for the diseases notified, he admits "the fact" that small-pox has been found to be most prevalent in the neighbourhood of the large London hospitals," and then, curiously enough, he rather complains of "a most unreasonable fear of the dangers which may arise from an infectious hospital." We think that "the fact" he refers to makes the fear of small-pox hospitals most reasonable. But, in maintaining the contrary opinion, Dr. SEATON goes on to state that it has been shown that the experience of the country towns is altogether opposed to that of London. We know of no such proof. But we do know that this same view of the harmlessness of London small-pox hospitals was held quite as stoutly as that relating to the country ones is now maintained, until the metropolitan hospitals were put to a test to which no other hospitals in country districts have been subjected. And further, whatever be the cause which leads to mischief around small-pox hospitals, we believe it has operated as regards several country as well as London hospitals. There was a large incidence of small-pox around the Oldham Hospital; the same has been alleged at Birmingham, and, curiously enough, although maps are issued showing the incidence of other infectious disease in various parts of the borough, the reports give no such information as to the localisation of small-pox. And again, a careful perusal of Dr. SEATON'S own paper before the Epidemiological Society as to small-pox in Nottingham leads us to believe that if the rate of attack per house in the different zones around the Nottingham Hospital had been calculated in the same method as that adopted by Mr. POWER in his masterly report on Fulham, the case of Nottingham would, in all probability, have afforded a striking proof of the truth of Mr. POWER'S conclusions. Until country small-pox hospitals have been subjected to the same crucial test as the metropolitan ones have been put to, the less that is said about them the better.

TRULY there is no limit to the application of the term "hysteria." The Clinical Society during its last session listened to the doctrine of hysterical hyperpyrexia. This was by an English observer, Dr. HALE WHITE; and now a French observer, M. DEBOVE, is discoursing on hysterical apoplexy. There is right and there is wrong in the use of this term to express the phenomena to which the English and the French physicians wish to draw attention. We think that the word "functional" would be preferable even when the ordinary phenomena of hysteria are under discussion. M. DEBOVE speaks of apoplexies due to the influence of lead, mercury, and alcohol as also hysterical. The essence of the controversy lies in the nutshell of a name. There are in the brain certain centres having certain functions, which may be deranged by organic and by non-organic causes—i.e., irremediable and remediable or removable causes. A hæmorrhage may abolish certain functions by placing *hors de combat* certain structures exercising those functions. It is conceivable that the same structures may be the seat of intrinsic disabilities leading to

Digitized by Google

an overaction or cessation of action. And the same structures may be excited to overaction or inaction by toxæmic conditions. Is there any good reason why we should style a paralysis "hysterical" because we cannot ascertain the cause that has led to the inactivity of the paralysed centre? If the etymologically unfit word is to be retained at all, its use should, in our opinion, be limited to describe those cases in which there is every reason to believe that the affection has been brought about as the result of an inherently faulty condition of the nervous protoplasm, such as is inferred when we recognise the existence of the well-marked neuropathic disposition. For all this, the case which M. DEBOVE described as hysterical apoplexy is full of interest. The following is an outline of the case. A man aged thirty-one, whilst walking away from the dinner-table, suddenly lost consciousness and remained in this state for twelve hours; no convulsions appeared to have occurred, the lumbar centres of the cord did not give way (or at least neither defecation nor micturition was noted), and the limbs remained relaxed. At the end of the period of unconsciousness the left side of the body was found to be paralysed, and there was absolute loss of sensation in the whole of the left half of the body, including the special senses. The paralysis of motion disappeared considerably in the course of a few hours, so that there was but some weakness on the next day. The hysterical, or, as we should prefer to call it, "functional," nature of the affection is proved by the circumstance that the defect of motion and the loss of sensation could be made to pass over to the opposite side of the body by the employment of any of those agencies that are ordinarily effective in the causation of the phenomena of "transfer," and by the further fact that the whole of the symptoms disappeared in the course of a few days. One more principle should be borne in mind: "hysterical" phenomena are not unfrequently met with in cases of genuine organic disease of the brain. It is important to add that M. DEBOVE'S patient was in the marine service, and had never been known to suffer from any phenomena that could be classed under the heading of nervous—surely an argument against labelling his case as one of hysterical apoplexy. But there is some consistency in M. DEBOVE'S method, for he apparently designates most functional paralyses by the same inappropriate adjective.

Annotations.

"Ne quid nimis."

THE GENESIS OF TYPHOID.

TILL within the last fifteen years Rome stood conspicuous among European cities for her exemption from gastro-enteric fever, and yet she had many of the conditions which favour the rise and progress of the malady—a town council whose neglect of sanitary law had passed into a by-word, and periodical overcrowding from the hordes of pilgrims that even in Dante's time formed a veritable "army" of conscientiously filth-despising, flesh-crucifying ascetics. With every facility for its being imported and effecting a foothold in the Eternal City, typhoid was known to Baglivi, Lancisi, Puccinotti, Valentini, Folchi, and other great Roman physicians only from foreign treatises or correspondents never in their own practice, whether private or in hospital. True, there were acute fevers, there were "subcontinuous remittents"; but their response to treatment, hygienic and clinical, proved their absolute non-connexion with typhoid. The Leonine City, for instance, was visited by a fever which, in Lancisi's time, swept away 2000 victims in three months, but which disappeared under the prompt measures of that eminent physician—the draining of the moat of Castle St. Angelo and the exhibition of Peruvian bark. Besides this fever described by Lancisi as "febris castrensis" from its association with the stagnant water of moat-defended garrison-towns, there was the "febris hemitritæa," or semi-tertian remittent, which Liebermeister has tried to classify under "typho-abdominal." But even this, both in symptoms and in response to treatment, was not a true typhoid, and is described by Petroni, a predecessor of Lancisi's in Rome, as occurring very rarely (*perraro*), and by Lancisi himself as only epidemic when an inundation of the Tiber had preceded it; while Professor Valentini, an eminent authority for the first half of this century, says of it: "Nostris temporibus fere nunquam observatur." The statistics of the Roman hospitals afford further proof of the city's immunity from typhoid till within the last decade or so, these hospitals lying low and very inferior in construction and sanitary appointments to those of London, or even Paris and Vienna, yet hardly ever exhibiting even an imported case of typhoid for the instruction of the students. But now all this is changed, and in the new quarters of the city which have sprung up since 1870 typhoid is getting far from rare. The introduction of English waterclosets into the Roman dwellings is, by common consent of the local physicians, the cause of this formidable importation. Dr. Fattorini has recently published an able essay on the genesis and propagation of typhoid in Rome, and traces the appearance of the disease to the sewage poison for the first time finding its way into the drinking-water of the inhabitants. "The ancient Romans," he says, "knew nothing of the microscope nor of bacteriology, but they had an intuition of this double source of infection, and they set themselves to protect their city from it by their marvellously constructed *cloacæ*, which promptly carried all excreta away from inhabited neighbourhoods, and by their equally marvellous aqueducts, which supplied every urban quarter with the purest water in such volume that it kept constantly flushed the *cloacæ* themselves. This hygienic practice they consecrated in their cult of the goddess Cloacina, and they sealed it with the physiological axiom: 'Ubi bonæ sunt aquæ, ibi bonus; ubi malæ, malus itidem est aer.' A part of this precious heritage, the aqueducts, abides with us their effete posterity, and it was precisely this which kept us in the health and strength we enjoyed, in spite of everything we did, by our effeminate lives, led amid corruption and dissipation, to spoil it. It was precisely that portion of the antique, supremely pure, potable water which chanced to remain to us, notably the Acqua Vergine, which maintained Rome up to the other day, even in her Ghetto, free from those terrible typhoid epidemics which in every other city have for centuries raged so fiercely and reaped so many victims." Dr. Fattorini then describes to his readers how the Acqua Marcia reintroduced into Rome in 1870, and distributed to the new quarters in scanty volume, has combined with the English watercloset system to convey the sewage effluvia from floor to floor of the dwelling-houses. Moreover, this Marcia water having lost its great original purity, lies in cisterns on these floors till it loses its initial coolness (12° C.), at which bacteria do not live, and rises in warm weather to 25°, or even 30° C.—a temperature most favourable to all manner of putrid fermentations. Dr. Fattorini urges the ædiles of modern Rome to insist on every house, before it is inhabited, being furnished with the ordinary means of preventing the drinking-water from communicating with sources of sewage

Digitized by Google

contamination, and in the meantime recommends all inhabitants of the Marcia-supplied quarters to use that water only in the boiling state for culinary purposes, and to drink nothing but the Acqua Vergine, which feeds the public fountains in such sparkling and exhilarating volume.

THE "CAN" AND THE "SHALL" OF WOMAN-CULTURE.

No physiologist will question the possibility of developing by appropriate stimuli, exercise, and food, any particular part or parts of an organism in such manner as to make it respond to the demands of its environment. Beyond doubt this mode of development is the natural process of evolutionary growth and modification. It must, therefore, be theoretically possible, as it has been abundantly shown to be practicable, that a female of the species *homo* shall be developed in respect to any one or more of her organic potentialities to a level with the male. And what has happened in the case of an individual may occur in any number of instances. In short, the difference between woman and man in respect to any of the brain or muscle functions is, as the difference between any two women or any two men respectively, one of development by training. The female is undoubtedly, from a developmental point of view, an animal in which the evolutionary process has been arrested or, more accurately speaking, diverted from the general to the particular, for special reproductive purposes, before the culminating point could be reached; moreover, it has been maintained that the controlling force as regards the determination of sex is one of procreative ascendency, the temporarily more exigent parent determining sex on the side of desire; the male parent selecting, in an evolutionary sense, female offspring, the female parent selecting or determining males. The explanation of the *modus operandi* of procreative exigency is that this exigency is the effect of preparedness to produce. The point to perceive is that the differentiation of sex is not in the nature of superiority or inferiority as regards the integrity of the animal organism, but one of special fitness, and therefore there are certain *plus* or *minor* qualities connected with sex which are the natural concomitants of the differentiation, but do not constitute disabilities. Thus the female is smaller than the male, unless smallness be an advantage in respect to locomotion, as in certain birds, when the apparent rule is not followed, because the real underlying and constant principle necessitates a change of policy, with the same object and a seemingly different, though actually identical, result. Meanwhile there is no physiological reason why the female should not be developed to proportional size equal with that of the male if suitable stimuli, exercise, and food be applied. We do not doubt that in a certain number of generations, women, if cultured as men are cultured, might be developed in all respects to the same proportions as men in respect to brain or muscle, or both; but we contend that if this were accomplished they would be *monstrous*. A masculine race of women would be as abnormal as an effeminate race of men, and in process of time the instinct of nature would assert itself, so that womanly women would feel the same contempt for masculinity in their sex as manly men feel for effeminacy in theirs; and when this instinct asserted itself, there would commence, involuntarily and uncontrollably, a reversion to the normal type, so in time the monstrosity of development would correct itself; though not, perhaps, until—as often happens in revertings to a lower type—the returns were carried too far, and the female unduly degraded for a time. There is evidence that this has occurred. As [illegible] individual woman or any number of women [illegible] ective in regard to organic capabilities, [illegible] must be [illegible] that she or they *can* do anything [illegible] similar organic capabilities is able to do; but the question *shall?* arises; and though we are not prepared to go the length of saying that the special powers of sex will be impaired by the general development, we are of opinion that the rule of natural fitness will be broken, and in the end so disadvantageously that Nature must and will interpose to restore the type by reversion. This we take to be the sum of the argument in explication of the question, "Can a woman do a man's work?" The subject is one which cannot be intelligently studied or discussed apart from the recognition of physiological laws and principles.

OUR INCREASING POPULATION.

HAVING, in his annual report on the parish of St. Mary's, Islington, announced that the death-rate for 1885 was the smallest on record, Dr. Meymott Tidy discusses the meaning of the facts relating to diminishing death-rates as affecting the population of England and Wales. The present population may be set down at 24,000,000, and the acreage of cultivated land at 30,000,000; there being thus one person to 1·25 acres, or about one-fourth the quantity of land per head of the population of Europe as a whole. But statistics show that 150 people are every year added to every 10,000. Reminding his readers that about twenty generations have passed since the Norman Conquest, Dr. Tidy asks what will be the result when twenty more generations of Englishmen are numbered among the dead; and he explains that at the present rate of increase there will then be a population of 27,220,000,000, who would require a place of abode of twenty earths if the then population were no more dense than the present one now is. Tracing the increase in population through its various stages, the report points out that in the reign of Henry VIII. the population of England, kept in check by wars and pestilence, numbered not more than 5,000,000, whilst in the early part of the reign of George III. it was about 7,500,000. Then came a period of commercial prosperity, and with this the population of England went up first to 10,000,000 or 11,000,000, and then to 16,000,000 at the period of the repeal of the Corn Laws. At the present time 24,000,000 have to be housed and fed in England and Wales; and in face of this fact we have to remember that our exports are things that cannot be eaten, whereas 50 per cent. of the food we require comes from abroad. Dr. Tidy doubts the healthy condition of a nation that cannot maintain itself, and he regards the present increasing population and declining trade as serious facts for the sanitarian and sociologist.

MUSCULAR ATROPHIES.

THE most commonly recognised muscular atrophies are those that result from disease of the spinal cord and nerves, as well as that variety which is due to simple disuse. The neuritic and myelitic muscular atrophies are remarkable for the rapid rate of the wasting. That which is the simple outcome of disuse is manifested gradually. The electrical reactions of the wasting muscles are of great interest, and serve to group the different varieties into at least two main classes. Inflammation of the spinal motor cells, or of their prolongations in the mixed spinal nerves, leads to rapid atrophy, and the nerves soon cease to respond and the muscles to contract to the faradaic current. In chronic spinal muscular atrophy, or progressive muscular atrophy, the reaction of the muscle to faradaism is retained so long as any muscular fibres remain. In this disease it would seem as though we had to deal with a degenerative affection of the whole muscular apparatus, for in many cases the whole length of the nerve-cells and fibres of the brain (pyramidal tracts), as well as those of the spino-muscular segment, are found to be wasted. In the amyotrophy resulting from arthritis, about the pathology of which some difference of opinion exists, the electrical reactions are generally

Digitized by Google

normal, but a change may be detected in some cases. As a general rule the wasting occurs in the entire length of the extensors of the joint affected, though other muscles moving the joint may be wasted, and occasionally the whole of the muscles of the limb are involved. The muscular atrophy that attends arthritis deformans of the multiple type is frequently remarkable. It has been ascribed, with the joint affection, to the influence of abnormal impressions from the generative organs acting on that part of the spinal cord corresponding to the muscular and arthritic atrophy. But it is quite as probable that the muscular wasting is the result of the joint disease, and of the same order as the amyotrophy resulting from an arthritis, however induced. It is supposed that the arthritic muscular atrophy is of reflex origin, due to the disturbance of some trophic nerve centre, irritated by the painful state of the sensitive nerve fibres. In addition to the amyotrophies already mentioned, there is a variety due to over-use; this is most frequently met with in feeble individuals, who use the muscles, generally those of the hands, unduly. But the list of muscular atrophies is not yet exhausted, for we have to recognise the idiopathic forms, of which the pseudo-hypertrophic paralysis is the best known. The simple idiopathic kind, in which the muscles waste gradually, without, so far as is known, any atrophy of the nerves or spinal cord, runs in families, and usually begins before adult life is reached. Some have even endeavoured to make another variety of this idiopathic group by separating those cases in which the atrophy begins in the face. Sometimes the amyotrophy accompanies hysterical paralysis, and cannot be ascribed to simple disuse, for the atrophy is frequently of rapid course in these cases. The same sort of atrophy of muscles is witnessed in the cases of disease of the spinal cord where the lesion does not anatomically affect the parts presiding over the nutrition of the wasting muscles. We must here suppose that some kind of morbid influence is exercised by the coarse disease of possibly the same kind as is transmitted to the trophic centres from diseased joints. The electrical reactions in this last class of cases are also generally normal.

SUFFOCATION IN A WELL.

A PAINFUL story of death from misadventure, which in this as in so many other cases means death from ignorance or carelessness, was investigated the other day by Dr. Danford Thomas. A prisoner in Pentonville Gaol volunteered, with a colleague, to descend a disused well for the purpose of removing pumps. The danger of such a proceeding is manifest, and it is reported that the authorities were warned of the danger, and the jury certainly appended a censure to their verdict. One of the men died and the other was so much affected that he had to go to a hospital. It is scarcely necessary to remind our readers that the utmost caution should be used before entering any well or confined space. Carbonic acid generates under a variety of conditions, and its action, even in small quantity, is not only poisonous but paralysing. The candle test is, when properly used, sufficient. If the candle burns clear and bright to the very bottom there is no danger, but if it does not go to the bottom there is always a possibility that carbonic acid, which is half as heavy again as air, may lie there, as in the celebrated Grotto del Cane, in which a man can stand while a dog is asphyxiated. It is commonly supposed that carbonic acid accumulates only in old or disused wells. This is a dangerous delusion. We were present a few years ago at an inspection of a new well on the estate of our lamented Editor, the late Dr. Wakley. The well had only been sunk a few weeks before in a country place remote from houses. It was loosely covered, and one of the men was about to descend for the purpose of inspection, when Dr. Wakley, with characteristic caution, insisted that a candle should be lowered first. It went out before it had gone six feet; and it is certain that if the man had gone down, as he proposed, he would have fallen lifeless to the bottom. The generation of carbonic acid below the surface of the earth is apparently capricious. The curious pits or caves, some of them more than a hundred feet in depth, which abound in the neighbourhood of Bexley, in Kent, contain no carbonic acid, as we can testify from personal experience, although they are said to have been excavated in prehistoric times; whereas, as in the instance already quoted, the gas may accumulate in a perfectly new chamber. The mere extinction of a flame is not a sufficient indication of danger. If the candle burns dimly there is risk, for the gas acts on living beings as on candles, and insensibility, or exhaustion tantamount to it, may be produced by a quantity of carbonic acid which would not immediately kill.

THE "BONE-SETTER" TRIUMPHANT.

A CASE of considerable importance to the medical profession was decided at the end of last month in the County Court of Cockermouth. The facts were briefly as follows. On June 27th, 1884, a solicitor named Nicholson injured his ankle, and sought the advice of Mr. Spurgin, in practice at Maryport. He remained under his treatment until the 16th of July, when, being dissatisfied with the results, he called in a "bone-setter," who, by the way, was not a duly qualified man. On the part of Mr. Spurgin it was contended that the said injury was only a severe sprain of the ankle, without fracture or dislocation, whereas the bone-setter alleged that the fibula was dislocated, and, further, that he reduced the dislocation. Judgment was given for the defendant (Mr. Nicholson), on the grounds that, according to the testimony of the defendant, "after a somewhat lengthened treatment by the plaintiff his pain and inability to move his foot rather grew worse, but upon the bone-setter operating upon his foot he felt the bone set right and obtained almost instant relief, and was in a short time able to walk as usual." The judge added "could this possibly have happened if the ailment had been a sprain?" He came to the conclusion it could not, and expressed himself "driven to the conclusion that it was dislocation, and not simply a sprain." His honour, with great frankness, gave as his reason for accepting the evidence of the bone-setter in preference to that of Mr. Spurgin and his assistant, that "there have been hundreds of cases where certified professional men have failed to discover the nature and cause of ailments in which uncertified men, or what are denominated 'quacks,' have succeeded in effecting cures." We cannot but think that the argument on this point was unsound, for to make the conclusion valid it ought to have been shown that uncertified men are more often right in their diagnosis and treatment than are duly qualified practitioners. But, apart from this, we maintain it is impolitic to set a greater value upon the alleged experience of a bone-setter than upon the opinion of a properly educated and legally qualified medical man. Having decided that the ankle was dislocated, his honour continued, "I have abundant authority for saying that any surgeon with a moderate knowledge of anatomy ought and might have discovered it." It is a pity Mr. Spurgin did not call medical evidence as to the probable nature of the accident, but doubtless he never dreamed of the judge discarding his professional opinion in favour of that of an unqualified man. We have not the slightest hesitation in saying the judgment was not warranted by the published facts of the case, whatever it may have been by the facts before the court. It is beyond all question that there never was a dislocation of the ankle in this case. The evidence of the defendant Mr. Nicholson, as well as that of the bone-setter, conclusively prove this; for had there been a dislocation, it is quite clear the foot would have been crippled too much

Digitized by Google

to allow of the patient walking in so short time as a week after the reduction of the dislocation. This is one of those cases which Sir James Paget, in an admirable clinical lecture, speaks of as "cases which bone-setters cure." The improvement that followed the manipulation by the bone-setter was clearly due to the rupture of an adhesion consequent on the inflammation and forced rest of the foot incidental to the sprain. From the report of the trial, we cannot find one single fact to show that Mr. Spurgin did not recognise the true nature of the case and treat it with sound judgment and skill. Every surgeon knows that a sprained joint needs rest, and equally that it may be necessary, in order to complete the cure, to use some force at a later period with a view to freeing the joint from impediments which restrict its movements. We commend these remarks to the consideration of the judge who tried the case, for we feel fully convinced that, had he been instructed in the natural history of a severe sprain of the ankle and its appropriate treatment, he would have found abundant proof that there had been no dislocation of the joint. Should his honour ever have the misfortune to meet with a similar mishap as Mr. Nicholson, we ask him to believe (and to act on the belief) that a legally qualified surgeon is more competent to treat a *surgical* injury than a "bone-setter," even though the latter be gifted with hereditary talent unto the fourth generation.

FATAL RESULT OF PEROXIDE OF HYDROGEN INJECTIONS.

A NORWEGIAN surgeon, Dr. Laache, has reported a case in which a fatal result followed an injection of peroxide of hydrogen into the pleural cavity. The patient was a man twenty-eight years of age, who had had a portion of the ninth and tenth ribs resected for empyema. The operation had been successful and the wound progressed favourably, and two months after the operation there remained only a fistula about an inch and a half long. In order to hasten the healing of this, hypodermic injections of a 3 per cent. solution of peroxide of hydrogen were resorted to, as this method of treatment had given very satisfactory results in two somewhat similar cases in which it had been tried. Six injections, each containing 0·8 cubic centimetre of the solution, were administered without any particular effect. At the seventh, however, the patient complained of pain and faintness, the pulse failed, the respiration became oppressed, clonic contractions occurred in the right arm, the head turned to the left, the jaws became tightly set, the face became cyanotic, and the patient died in ten minutes. The necropsy, which was not made till forty-eight hours after death, revealed nothing very striking. The heart was dilated, and contained liquid blood without air bubbles; some ecchymoses were found in the parts of the left lung, which were adherent to the chest walls. In the fourth ventricle of the brain an ecchymosis the size of a pin's head was seen. A number of air bubbles were present in the blood of the hepatic veins, and some were seen on cutting into the spleen and kidneys. The cause of death was therefore by no means clear. Dr. Laache suggests that it may have been the small extravasation in the fourth ventricle or shock. Dr. Wulfsberg, who took part in the discussion on the case at the Christiania Medical Society, thought it was probably due to the introduction of the drug into the circulation. He thought that the strength of the blood current might have carried the peroxide, if introduced into a vein, through the right heart and lungs almost unchanged, but that afterwards more oxygen might have been disengaged than the blood could absorb, and bubbles were thus produced, which may have been the immediate cause of death. Where animals have been subjected to injections of air into the veins bubbles are not always found in the blood. In these cases Dr. Wulfsberg thinks that death has been due to paralysis of the heart, for when examinations have been made immediately after death bubbles have been found in the coronary arteries. As so long a time had elapsed before the necropsy in Dr. Laache's case, these might have been absorbed.

THE TRAGEDY AT FINSBURY PARK.

ON the 20th ult., an inquest was held by Dr. Danford Thomas concerning the deaths of Henry George Underwood, aged fifty-seven, and Jane Underwood, his wife, aged fifty-four. From the evidence it appeared that on Sept. 16th the son of deceased, on returning home late in the evening found the body of his mother lying on the back in her bedroom in an almost naked condition. Expecting his father to come in shortly, he went to bed; but in the morning, finding that his father was not about, and the body of his mother in the position in which he left it overnight, he raised an alarm. On a search being made, Mr. Underwood was found dead in the watercloset, with his throat cut. A razor was grasped in his hand, and the door was fastened on the inside; so there could be no doubt that he had taken his own life. In his case a verdict of suicide during a fit of temporary insanity was returned. It was naturally suggested that he had first killed his wife and immediately afterwards cut his own throat, the supposed motive being an insane impulse caused by his depressed state of mind consequent on the long-continued drunken habits of his wife. The body of Mrs. Underwood was covered with bruises of different ages. Round the neck a silk handkerchief was found loosely tied. On the front of the neck were some marks which might have been produced by an attempt at strangulation; and on the neck, face, and ears were a number of recent abrasions. The lungs were congested, but not particularly engorged. The liver was cirrhotic, and the stomach contained "a quantity of port wine." The deceased was intoxicated in the morning of the day on which she was found dead; after that she was not seen alive. There being some doubt as to the interpretation to be put on the evidence concerning the marks of injury, the inquest was adjourned, and a second necropsy was ordered to be made by an expert pathologist. At the adjourned inquiry on the 27th ult. Mr. Pepper stated that in his opinion the marks on the neck, face, and ears were scratches made by deceased in attempting to free herself from the constricting force applied to the neck. There were three bands of congested skin on the front of the neck, tapering away at the sides, and over them the skin was slightly excoriated. On the right side of the neck and at the nape were two recent bruises. The trachea and windpipe were deeply congested. On the right of the umbilicus was a bruise the size of the palm of the hand, which at the first examination was observed to be purple, but which a few days later had become bright-red in the centre. The bruise was a recent one, and the change in colour was evidently due to the oxidation of the colouring matter of the blood, as this had become diffused in the substance of the skin. Two or three coils of intestine underlying this bruise were deeply congested, but they presented no signs of constriction, ulceration, or rupture, and it appeared certain that the same injury had bruised both the abdominal wall and the bowel. As to the exact sequence of events preceding death it was impossible to speak with certainty, but in all probability the woman was strangled whilst in a helpless state of intoxication, and possibly after she had received a blow in the abdomen, either by falling heavily on some solid body, or at the hands of another person. That no great violence was employed to effect strangulation was proved by the comparative slightness of the marks made by the constricting force, especially as the state of nutrition of the tissues was such as to favour the easy

Digitized by Google

development of bruises. The jury returned a verdict that deceased died from asphyxia caused by constriction of the neck whilst in a state of deep intoxication, but that there was not sufficient evidence to show by what means the strangulation was effected.

SCARLET FEVER AT NEWQUAY.

THE correspondence in *The Times* on scarlet fever at Newquay has been continued during the past week, and has sufficed to show that the prevalence of this malady was probably in the first instance due to milk infection, and was continued through the suppression of information by lodging-house keepers and others. *The Times* has certainly taught these persons a lesson that their own interests are not best served by such conduct, and if the same powerful voice still continues to give publicity to similar occurrences, lodging-house keepers will find that their own interests are absolutely dependent upon the measures they adopt for ensuring the welfare of those whom they receive, and will be forced to have more regard for the safety of those who visit summer resorts. A system of notification of infectious diseases faithfully carried out is the chief step which must be taken, but more good would come if those who provide lodging accommodation would voluntarily agree to a register being kept at the office of the sanitary authority, which could be consulted by visitors, and give all necessary information as to the sanitary condition of such houses, and as to their freedom from infection. Doubtless, concealment is due to the fear of losing profits which would otherwise be made during the season, and it is therefore necessary that there should be some provision for reducing this loss; this could best be done by the organisation of a system of insurance which would guarantee the payment to the letter of lodgings of some sum as compensation for loss incurred through the house remaining unoccupied on account of the occurrence of infectious disease within it. Such an organisation might also assist in checking the importation of infectious persons. "Medical Officer of Health," in a letter which forms part of the correspondence to which we have referred, writing on the scope and intention of the 90th section of the Public Health Act, 1875, says that this clause applies to houses of the artisans and labourers' class. It is true that this limitation exists as a matter of practice, but there appears to be no reason why these regulations should not be made to apply to houses of all classes which are thus let; the limitation hitherto observed has been due to the belief that they were not required for any but those occupied by artisans and labourers.

THE EASTERN GIPSY 'CRUX."

AN amusing illustration of the difficulties of self-government is afforded by the dead-lock to which matters have come in connexion with the Eastern—it is absurd to call them *Greek*—gipsies, who, having been landed in this country, can neither be got rid of, nor, as it would seem, reduced to the condition of a tolerable integer in the sum total of the population. An autocratic government would simply have shipped them to some other shore and landed them either by stealth or defiantly. Under our milder system of self-rule, we are struggling with the difficulty of solving the question what to do with these children of Esau. The serio-comic element of the situation comes out strongly in a charming succession of incidents. The local police stop them while travelling, and finally direct them to a place of encampment on certain land, the owner's permission being either asked by, or volunteered to, the chief constable. After a while the medical officer of health strives to enforce sanitary provision, and, failing in his laudable endeavours, reports the existence of a nuisance. Whereupon the owner of the property is to be indicted for a nuisance! Could anything be more absurd than this business throughout? It doubtless seems perfectly proper to the authorities concerned. Their sole concern is to get rid of the nuisance. It was even suggested that some benevolent person should provide a cart, and these gipsies could then "move on" on the Queen's highway, where no one would stop them. A vagrant band has no special interest for local sanitary authorities, provided only that it keeps moving. Thus it is that public health is reduced to the position of a football which may be kicked about at pleasure, and the only aim of the players is to keep it out of their bounds, where else it may go being a matter of perfect indifference. The aim of the medical officer to establish sanitary conditions in this case was frustrated at the outset by the mere objection of the owner of the property to allow the erection of even movable closets!

DRESS OF SOLDIERS ON FIELD SERVICE.

COLONEL TULLOCH, in a recent number of the *Illustrated Naval and Military Magazine*, has given a description of an extemporised dress which was adopted in the battalion of the Welsh Regiment under his command in South Africa, in anticipation of being sent on field service. The clothing of the men was the same as in England, and was ill suited for active service during the hot season in Natal; the colour of the scarlet kersey was also considered to be objectionable, and there was not time to obtain suitable light clothing from England or khakee from India. An additional stout grey flannel shirt was therefore issued to each man, to be worn as a blouse over his other shirt instead of the kersey. Shoulder straps of cord were put on to retain the belts in position. This dress had the advantage of being loose about the neck and throat, cooler than that which it replaced, and of a less conspicuous colour. It seems to be remarkably well suited for the purpose for which it was devised, and would doubtless have added materially to the comfort of the men in the field. Colonel Tulloch also suggests the removal of the metal ornaments from the helmets, or, still better, the substitution of a pith helmet for that now in use. These were worn by the "Royals" at Hong-Kong and on field service in China twenty-five years ago, and have the great merits of being light, cool, and inexpensive. Colonel Tulloch's experiment might prove practically suggestive to those in authority who are responsible for the clothing of the soldier.

SUFFOCATION; MUSSEL POISONING; HEART DISEASE; SYNCOPE?

THE evidence tendered before the coroner at Westgate, Rotherham, on Sept. 28th, concerning the death of a labourer named John Sykes, aged thirty-six years, was consistent with death having occurred from one or more of the causes mentioned at the heading of this note. Deceased had "rheumatic fever" three or four years ago, but whether it left any cardiac mischief was not known. On the day before his death he got drunk and vomited. He was put to bed in the evening, and at half-past four in the morning he was found dead. It seems not improbable that vomiting occurred whilst deceased was in a state of partial consciousness, and that he was suffocated by some of the vomited matter getting impacted in the air passages. Or the exhaustion consequent on persistent vomiting in a person of weak bodily powers may have terminated in a fatal fit of syncope. Or, again, there may have been cardiac valvular disease, and the strain on the heart incidental to vomiting may, together with this, have determined the issue. We do not attach much value to the fact that he had been eating mussels, for no one else seems

Digitized by Google

to have suffered any ill effects from this possible source. Lastly, death may have ensued from acute alcoholic poisoning. The coroner left it to the jury to say whether it was desirable to have a post-mortem examination made, but "the good men and true" were satisfied, and returned a verdict to the effect "that death took place from natural causes, probably from heart-disease"—a most unsatisfactory ending to the inquiry, as we think. If, as seems likely from the evidence, deceased was so intoxicated as to necessitate his being carried home, someone ought to be made answerable for having supplied him with a poisonous quantity of alcohol, or with having served him with more "drink" when he was already inebriated. It is true the matter was one for the jury to decide, but a little persuasion and guidance on the part of the coroner generally suffices to induce them to be led in the desired direction; and in this case, we think, the inquiry should have been adjourned for further medical evidence—viz., that which could only be obtained by a necropsy.

THE DIRECT REPRESENTATIVE FOR IRELAND.

DR. KIDD'S candidature has been pressed forward by a large meeting of the profession at the Shelbourne Hotel on the 29th ult. Resolutions were proposed by Drs. Gordon, Aquilla Smith, and R. McDonnell, the chair having been filled by Sir George Porter. The Executive Committee consists of Drs. Bennett, Corley, Gordon, Mapother, and Wm. Stoker. The only objection to Dr. Kidd is that he is not a general practitioner; that Dublin and its corporations are already amply represented. If the new seat is to go to a dignitary of one of the colleges, it might as well not have been granted. It rests with the practitioners of Ireland to show that they are capable of promoting successfully the election of one of their own number.

"FOUND DROWNED."

NOT long since the body of a young woman named Elsie Corfe, of highly respectable position and family, was found drowned in the river at Bath. There was no evidence to show how deceased got into the water, or how her death was occasioned. On the evening before her body was discovered in the early morning, she appeared in good health and spirits, and there was utter absence of known motive to commit suicide. The fatality has caused considerable excitement in the neighhourhood, where deceased was well known and respected. We cannot help thinking that it would have been a wise procedure on the part of the coroner's court if a post-mortem examination had been ordered. The cause of death would then have been elicited, whereas the case now stands—"a mystery"—just as the jury received and dismissed it.

DR. VON HOLST ON NITRO-GLYCERINE.

DR. L. v. HOLST reports in a St. Petersburg journal a number of observations on the action of nitro-glycerine on heart diseases. He considers that it is especially useful where little or no serious organic change in the heart muscle or valves has taken place, and where the affection is mainly due to a debilitated condition of the organ. In angina pectoris Dr. von Holst has found nitro-glycerine very useful; in one case, indeed, it produced a permanent cure. He recommends recourse to this drug instead of to camphor and musk in cases where great cardiac weakness threatens immediate danger to life. He considers that the diuretic action is not due to any direct stimulation of the kidneys, but is a consequence of the regulation of the heart's action. He finds that dropsy, if due to heart weakness, diminishes under the use of nitro-glycerine, but that the renal form is uninfluenced by it. With regard to the dose, the author advises that small quantities should be given at first, and increased gradually according to the effect on the particular case. The preparation he uses is a 1 per cent. alcoholic solution, and of this he gives from one to six drops three times a day.

FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.

AT the annual general meeting of the Faculty on Monday last, Dr. James Morton, Professor of Materia Medica in Anderson's College, was elected president. Dr. Morton has fairly earned the compliment thus paid him, and the dignity and interests of the Faculty will be safe in his hands. A special meeting was held at the close of the annual meeting, for the purpose of disposing of the case of the "Erring Fellow," whose name is associated with a much-advertised liniment. The Fellow in question was suspended from the Fellowship for a period of six months, as, notwithstanding the facts that he had professed submission to the will of the Faculty, acknowledged his error and made an abject apology, and had also promised to withdraw from all connexion with the liniment by Sept. 1st, the preparation was still advertised and purchasable at the time of the meeting of the Faculty. The Faculty deserves credit for the manner in which it has dealt with this case, for, while it acted with energy, it gave every opportunity to the offender to withdraw from his unfortunate position, and proceeded to extreme measures only when it was seen that the dignity of the profession, as represented by the Faculty, could be maintained in no other way.

THE JUBILEE OF HARVARD UNIVERSITY.

ON the 7th of November next, the Harvard University of Cambridge, Massachusetts, will have completed its 250th year, and it is proposed to celebrate the event in a suitable manner from the 6th to the 8th of that month. The University was established by an Act of the Colonial Legislature, and a certain John Harvard so liberally endowed it that it was decided to give the new institution his name. The jubilee will have great interest to the members of the medical profession, for this University has taken a leading part in the education of medical men for the Eastern States of America; and it has particularly distinguished itself by its persistent efforts to raise the standard of medical education. Its medical degrees have been very highly valued, and all friends of higher medical education will rejoice to know that age has in no way impaired the usefulness or the vigour of the University. With one exception, Harvard is the oldest university in the New World. Nearly 100 years before, in 1551, the Emperor, Charles V., established the University of St. Mark's at Lima.

BLIGHT ON AUTUMN AND WINTER GREENS.

THE value of green vegetables as an article of diet was recognised a century and a half ago by Arbuthnot, physician to Queen Anne, who in a treatise "On the Nature and Choice of Aliment," which was published in 1732, writes that "of alimentary leaves, the *potherbs* afford an excellent nourishment; amongst these are the cale or cabbage kind." Few things add to the relish of the poor man's dinner more than an abundance of well-cooked cabbage. "Bacon and greens" are proverbially popular. The old and general idea that green vegetables act beneficially in counteracting a disposition to what are popularly known as scorbutic affections is confirmed by modern experience. Thus any lessening of the supply or deterioration in quality of winter vegetables of the cabbage tribe is a subject of regret both to poor and well-to-do persons. The present autumn has been very favourable to the development of the species of blight

Digitized by Google

or aphis which attacks the cabbage tribe in particular. These diminutive insects prey upon the plants and so stunt their growth that gardeners are much concerned about their autumn and winter vegetables. In spring the aphis commits great havoc among young cereal plants, but in autumn, which is a period of active propagation, it attacks chiefly garden vegetables. It is a curious fact in natural history that the aphis propagates after fecundation for eight or nine generations without intermediate fecundation. "L'influence d'une prémière fécondation s'étend ainsi sur plusieurs générations successives." So writes a French naturalist; and it is calculated that a single mother may be the means of producing five thousand million offspring in the course of a few generations of ephemeral existence. These numbers account for the havoc such diminutive creatures can cause.

THE RETIREMENT OF SIR HENRY ROSCOE.

THE Victoria University, formerly Owens College, Manchester, sustains a great misfortune in the resignation of Sir Henry Roscoe. For many years Sir Henry has been recognised all over the civilised world as one of the greatest scientific men of our age. His researches have added chapters to the history of chemistry, his writings have adorned it, and his teaching has equipped a host of brilliant and useful scientific workers and successful teachers. His uniform courtesy, and the ready help he has afforded to all who sought it, have procured him high esteem among men, and when he was elected to a seat in Parliament all lovers of science rejoiced. The great empire of science is but imperfectly represented in England, and all felt that in Roscoe it had gained a worthy supporter. It is no doubt the pressure of Parliamentary duties which has led to the loss with which the Victoria University is threatened. We say threatened, because we are inclined to hope that even at the last moment Sir Henry Roscoe may be induced to reconsider his determination. Of course his Parliamentary duties would diminish considerably the time he could devote to the work of personal teaching in Manchester, but he could still deliver the most important part of the course of lectures, and his great reputation and experience and his power of organisation would still be at the service of the young University. The details of teaching could easily be carried out by others, but no one can replace Roscoe as a head. Doubtless the University authorities see all this as plainly as we do, and will do their utmost to prevent their most distinguished ornament from leaving them.

RELATION OF MEDICAL MEN TO DENTAL QUACKERY.

WE have had a matter of professional etiquette referred to us lately. A medical man writes saying that he was called in upon two occasions to administer chloroform to patients by a man who practises dentistry, but who, he has since been informed, is not registered, and our correspondent wishes to know what course he should pursue in future. There can be only one possible answer. He should absolutely refuse to attend. To associate in any way with one who is liable to prosecution, should he ever call himself a dentist and yet practises, must bring discredit not only upon himself but upon the medical profession generally. We will go further and say that no medical man should allow his name to be connected in any way with dental quackery or advertisement. Dental specialists have for years worked hard, and with success, to raise their professional and social status, and they look to their parent—the medical profession—to help them by not encouraging irregular dental practitioners.

ROYAL UNIVERSITY OF IRELAND.

BY the death of the Rev. J. Kavanagh, who was accidentally killed last Monday, another vacancy on the Senate of the Royal University has arisen. The deceased met his death in a singular manner. While performing service in the chapel a statue on the canopy of the altar, weighing about 40 lb., fell, striking the unfortunate clergyman, and precipitating him with considerable violence to the ground. This caused a fracture of the skull, and an injury to one of the branches of the temporal artery, which caused death in less than an hour. It is probable that to the names already mentioned as candidates for a seat on the Senate may now be added that of Dr. Knight, who may be induced to come forward.

TREATMENT OF TUBERCULAR MENINGITIS.

THE *Revue de Thérapeutique*, after stating that tubercular meningitis kills 25,000 persons every year in France alone, and quoting a passage from Jaccoud, in which he speaks of the powerlessness of medical men to cope with this terrible disease, cites some recent observations of a Swedish physician, M. Warfwinge, on the marvellous effects of a 1 to 5 iodoform ointment rubbed into the previously shaved head in quantities of seventy-five grains, night and morning. During the interval, the head was covered with an oilskin cap, which was secured by a bandage. M. Warfwinge treated five cases in this way, with a successful result in every case. The first case was treated for seventeen days, the second for nineteen, the third for thirty, the fourth for thirty-two, and the fifth for nine days only. Ordinary remedies were given in addition for any complications which arose, but M. Warfwinge attributes the successful results to the iodoform alone.

A STEP IN THE RIGHT DIRECTION.

OUR correspondent in Rome writes:—"The Hygienico-sanitary Commission has sent in its report to the Minister of the Interior, and that functionary has accordingly issued a circular to all the Italian communes, requesting them to furnish him with scientifically ascertained particulars of their water-supply, which the aforesaid commission had animadverted on as being bad, suspected, or insufficient. This step, he says, is taken with a view to providing every commune throughout the peninsula with sound potable water, and to invoking, if necessary, the authority of Parliament *ad hoc*. Such announcements are reassuring as to the public health of Italy, especially if taken in connexion with her fast-waning belief in quarantine by sea as well as by land."

ARMY MEDICAL SCHOOL.

THE winter session of the Army Medical School was opened on Friday, the 1st inst., when the introductory address was delivered by Surgeon-General Sir T. Longmore, C.B., Professor of Military Surgery. There were sixty-six surgeons on probation present, forty-one being candidates for commissions in the British Medical Service and twenty-five in the Indian Medical Service.

LOCAL AUTHORITIES.

MR. T. HARNESS HARRISON appears to have read at the Congress of the Sanitary Institute a paper which condemns, in terms not of the mildest, the motives and actions of members of local authorities. While expressing the opinion that the Public Health Acts are fairly satisfactory measures, he says that the bodies who administer them consist largely of men whose object is to frustrate their operation—these members, together with those who are passive, making 95½ per cent. of the total number. We do not doubt that this

Digitized by Google

estimate may be true for certain authorities. There are some who have earned an unenviable notoriety for their opposition to sanitary measures and their treatment of officials whose duty it is to carry the law into effect; but the progress the country has made during the present century, the large sums of money spent in public sanitary works of water-supply and drainage, are themselves evidence that local authorities as a whole are not backward in their duty. More harm than good is done by neglecting to recognise the benefits many districts have received at the hands of local representatives; condemnation should be reserved for those who are alone to blame.

MORE CANDIDATES FOR DIRECT REPRESENTATION IN ENGLAND.

MR. JOHN PAGE HENTSCH writes us to say that the members of the Medical Alliance Association and others have invited Mr. R. H. S. Carpenter and Mr. George Brown to stand as candidates for the Direct Representation seats in the General Medical Council, on the ground of the services of these gentlemen in connexion with attempts to prosecute illegal practice. Both of them have accepted the invitation. Whoever be the candidates returned, it will be their duty to use the powers of the Council and of the Act to the utmost in discouraging and punishing illegal practice.

THE SANITARY ASSOCIATION OF SCOTLAND.

THE twelfth annual meeting of this Association was held last week at Paisley, under the presidency of Mr. William Mackison, C.E. Two excellent papers were read by sanitary inspectors. "The Higher Aspects of Sanitation" were discussed by Mr. George A. D. Mackay, who gave some interesting statistics of the proportion of the total number of families living in one room in eight Scotch towns; while Mr. George McKay contributed a paper on "Ancient and Modern Sanitation," and showed in a tabular form the percentage of improvement in the death-rates in different districts in Scotland, and concluded with a number of suggestions, having as their object the promotion of sanitary work. The published accounts of the meeting appear fully to justify the statement of the chairman, that never was there a time when so much was being done to remedy existing sanitary defects as at present.

DENTAL CARIES IN BAKERS.

PROF. DR. HESSE of Leipsic, in the *Deutsche Monatschrift*, points out the deplorable condition of the teeth of bakers, and says that he is often able to tell the profession of the patients by the condition of their teeth. The caries is soft and rapidly progressive. The principal parts attacked are the labial and buccal surfaces of the teeth, commencing at the cervix and rapidly extending to the grinding surface. The approximal surfaces do not seem to be attacked more than in other patients. He believes the disease to be due to the inhalation of flour-dust, the caries being caused by the action of an acid which is formed in the presence of fermentable carbohydrates.

CARE AND EDUCATION OF IDIOTS.

AT the congress of those in charge of idiots held last month in Frankfort, Dr. Wulff, director of the asylum at Langenhagen, spoke strongly of the great importance of good nourishment for the inmates of such institutions, the meals, which should if possible number five daily, requiring skilled supervision, and the idiots being attended to by intelligent and careful persons. Dr. Berkhan, of Brunswick, spoke on Cretinism, and demonstrated the points of resemblance of a cretin's skull to the skulls of microcephalic subjects and Aztecs. He dwelt upon the diminution in cretinism which had already been produced by better attention to the nourishment of children in their earlier months and improvements in their surroundings. Dr. Barthold, director of the M.-Gladbach Asylum, read a paper on the Education of Idiots, showing how the doctor and the schoolmaster must work hand in hand. Suggestions were also made for forming classes for children of weak intellect in large towns; and Dr. Sengelmann, of Alsterdorf, read a paper on the Training of Teachers and Attendants for Idiots It was decided that the next place of meeting should be Brunswick.

TUBERCULAR ULCERATION OF THE VULVA AND VAGINA.

THE current number of the *Viertel. für Dermatologie und Syph.* contains a paper on a rare case of extensive ulceration of the vulva and vagina, by Dr. H. Chiari. A lithographed plate shows the extent and shape of the ulceration in the parts as removed from the patient, aged thirty Most of the internal organs of the body were the seat of chronic tubercle—lungs, bronchial and mesenteric glands, intestines, left suprarenal body, cerebral meninges, liver, spleen, and kidneys. The manner in which the infection of the vulva was effected is discussed, and the suggestion made that the germs from the intestinal disease may have been accidentally inoculated on the site affected. It should be stated that the uterus and its appendages were free from disease, and that the patient was a nullipara.

THE CHOLERA IN EUROPE.

THE cholera is steadily diminishing in Italy, and intelligence as to fatal attacks is almost entirely limited to the south of the kingdom. The disease still clings to the Bay of Naples, although it is much less severe than formerly. In the Austro-Hungarian Empire some fresh places have been attacked, and the malady is still fatally prevalent at Trieste and Pesth. In Pesth the fatality is now reduced to about four a day; and Szegedin, where twenty-eight cases and eleven deaths occurred in the forty-eight hours ending the 5th inst., is the only place where the disease shows any important increase. There are serious accounts of the ravages committed by cholera in Seoul, Corea.

MANSION HOUSE CHARITIES.

THE Hospital Sunday Fund has now reached a total of £40,000, and there are still fifty-four collections from churches and chapels to come in. Adding this to £78,0000 subscribed for the unemployed poor of London, nearly £120,000 has been raised for strictly metropolitan purposes, not to mention £6500 raised for the relief of the sufferers of the appalling earthquakes of Charleston and Greece. The Mansion House authorities must be congratulated on such results, especially when the badness of the times is considered.

FOREIGN PROFESSORIAL APPOINTMENTS.

THE following *agrégés* have been appointed for eight years to lecture on their respective subjects in the different Faculties of Medicine in France:—*Paris:* MM. Quenu and Poirier, Anatomy and Physiology. *Bordeaux:* M. Ferré, Anatomy and Physiology; M. Nabias, Natural History. *Lille:* M. Assaky, Anatomy and Physiology; M. Barrois, Natural History. *Lyons:* MM. Rodet and Jaboulay, Anatomy and Physiology. *Montpellier:* MM. Gilis and Tapis, Anatomy and Physiology. *Nancy:* MM. René and Nicolas, Anatomy and Physiology.

Buda-Pesth.—Drs. Israi and Bakó have qualified as privat-

Digitized by Google

docents for Laryngology and Diseases of Urinary Organs respectively.

Prague (Bohemian Faculty).—Dr. Joseph Thomaier has been appointed Extraordinary Professor of Special Pathology and Therapeutics.

St. Petersburg.—Dr. A. Pöhl has been granted the title of Honorary Professor of Medical Chemistry in the Princess Helena Paulovna Clinical Institute.

Würzburg.—The names of Professors Schörnborn, Trendelenburg, and Miculicz are those selected for the vacant Professorship of Surgery.

AT a recent meeting of the Glasgow Town Council an account was given of an outbreak of scarlet fever which is likely to promote the adoption of measures for the notification of cases of infectious disease. Scarlet fever has, it appears, attacked a number of persons receiving milk from a particular dairy, forty-four cases occurring among the milk consumers. A child suffering from this disease was found at the dairy, but the parents refused to permit its removal to hospital because their own medical man had declined to certify to it. For the protection of the public the dairy was closed, the premises fumigated, and the milk found upon them destroyed.

IT will be seen from our advertisement columns that the inaugural dinner of the Glasgow University Club, London, will take place at the Holborn Restaurant on October 22nd, at 7 P.M. The hon. secretaries are Dr. Heron, 57, Harley-street, W., and Mr. McIlraith, 3, Furnival's-inn, E.C., of whom tickets may be had.

AT the Westminster Hospital, Mr. Arthur Marmaduke Sheild, M.B., F.R.C.S., has been appointed assistant-surgeon, in place of Mr. Boyce Barrow, who has resigned; and Mr. James Black, F.R.C.S., has been appointed aural surgeon.

THE MEDICAL ACT, 1886: FOREIGN AND COLONIAL PRACTITIONERS.

BY A BARRISTER-AT-LAW.

THE Medical Act of the present year restricts the right of practising in the colonies which our registered practitioners have hitherto possessed; and it prescribes terms upon which both colonial and foreign practitioners may be admitted to registration in the United Kingdom.

Under the Medical Act of 1858 (Section 31) a registered practitioner had the right to practise, according to his qualification, and to recover his fees in any part of Her Majesty's dominions. A subsequent Act (the Medical Act of 1868, Section 3) enabled every colonial legislature to require such practitioner to register, as a condition of practising, within its jurisdiction; but it left him entitled to registration upon payment of the proper fee, and therefore (though in the requirement of a fee there may have lurked some possibility of obstruction) it left his right to practise unimpaired. In future, however (from June, 1887), though all existing rights of individuals are reserved, the right of our registered practitioners to practise in the British possessions is made "subject to any local law" (the Medical Act, 1886, Sections 6 and 25); it will exist wherever, in the British empire, and so long as, there is no local law regarding it; but every local legislature may impose conditions upon it, and may even, if so disposed, exclude it altogether.

In this, no doubt, a concession—a large one, too—has been made to colonial practitioners at the expense of practitioners registered in the United Kingdom. To deter them from pressing for an illiberal use of it, there are the conditions upon which they in their turn, and foreign practitioners also, are by the recent Act enabled to claim registration in the United Kingdom. Broadly speaking, this Act provides for a sort of reciprocity, as regards the right to practise and recover fees, between the United Kingdom on the one hand, and foreign countries and British possessions on the other.

The decision to admit any colony or foreign country to the benefit of the Act will be made by the Queen in Council, but this will be preceded, no doubt, by communications or negotiations, and probably by some more or less formal compact, between the colony or foreign country and our Colonial or Foreign Office. And any British possession or foreign country may, by order in Council, be declared to be a British possession or foreign country to which the Act will apply (from a day named in the order), if it affords to the registered medical practitioners of the United Kingdom "such privileges of practising as to Her Majesty seem just." (Section 17.) Till this is done for a colony or foreign country no right will accrue to any practitioner holding its qualifications. And this done, it will fall to the Medical Council to decide what degrees or diplomas, or combinations of degrees or diplomas, granted by the colony or foreign country can be recognised as furnishing a sufficient guarantee for the knowledge and skill required in the efficient practice of medicine, surgery, and midwifery. It should be said, however, that where, in working the Act, qualifications which have not been thus recognised are tendered to the Medical Council and rejected by it, the claimant of registration may appeal to the Privy Council, and that the Privy Council may order his qualifications to be recognised. (Sec. 13—1, 2.)

The provision that may so be made in favour of any colony or foreign country may be revoked by subsequent order in Council, and may thereafter be renewed. Rights acquired under an order will not be prejudiced by its revocation; but on its revocation the country affected will fall out of the list of countries to which the Act applies, so that no further claim to registration can be received from persons holding its diplomas or degrees.

The Act provides (Section 14) that the Medical Register shall in future contain a list of colonial practitioners and a list of foreign practitioners, and it allows those who are so entitled to be registered in both lists. For the phrase "colonial practitioner" does not in the Act mean a practitioner of colonial birth, but a person, wherever born, who holds colonial diplomas, granted in a colony to which the Act has been made applicable, and recognised by the General Council; who is by law entitled to practise medicine, surgery, and midwifery in the country which gave him his qualification; and who, moreover, fulfils certain other conditions. And, similarly, the phrase "foreign practitioner" extends to all persons, wherever born, who hold recognised foreign diplomas, granted in a country to which the Act applies, who are by law entitled to practise as aforesaid in the country which granted them, and who fulfil certain prescribed conditions. An applicant for registration in either list must prove his qualification and right to practise as above mentioned, and also that he is of good character, to the satisfaction of the Registrar of the General Council. Thereafter, the "colonial" applicant must prove, to the satisfaction of the same functionary, that he obtained his qualification either (1) at a time when he was not *domiciled* in the United Kingdom, or (2) in course of a continuous absence from the United Kingdom lasting for not less than five years (these are the continuing and more important provisions); or (a transitory provision) that when the Act became applicable to the country from which his qualification is derived he was practising medicine and surgery (or a branch of either) in the United Kingdom, and that he had been so practising, in the United Kingdom or elsewhere, continuously for ten years preceding at least (Section 11). The "foreign" applicant, if he is a British subject, whether a native of the United Kingdom or a colonist, is under precisely the same conditions. If he is not a British subject, proof of that fact suffices for him (Section 12). Registration in either list, where a claim to it has been established, will be granted, without examination, on payment of a fee, not exceeding £5, to be fixed by the General Council. That there may be an appeal to the Privy Council as regards the qualification tendered has already been mentioned. There may be an appeal, also, when registration is refused on any other ground (on a question of character, for example, or on a question of domicile), and the Privy Council may overrule the decision of the Registrar.

Of the transitory provision for the case of persons practising in the United Kingdom when an order in Council comes into force, and having qualifications recognisable under the order, all that need here be said is that while, on

Digitized by Google

the one hand, there will be no inquiry as to the circumstances in which they obtained their qualifications, they must, on the other hand, have been at the date referred to in practice continuously for not less than ten years. The meaning of the proviso is plain enough, and it is with that only that this article is concerned. As to the continuing provisions, a foreigner of good character claiming on a sufficient foreign qualification will always have an easy task, having merely to prove that he is not a British subject. In other cases the question of domicile may now and then raise a difficulty. The word "domiciled" is of course used in the Act in its technical meaning; and (though that is not to be explained briefly) it seems necessary to say that, in the legal sense, one may be domiciled in England though not a resident in it, or a resident in England without being domiciled in it. A man's domicile is, to begin, in the country of his origin, and mere absence from that country, however prolonged, will leave his domicile still there; for a change of domicile, he must be absent without thought of returning, and resolved to spend his life in some other country in which he is settled. It is needless, however, to forecast the questions of domicile that may arise. Here it is enough to say that, in general, a person born and bred in the United Kingdom will, as being domiciled in the United Kingdom, be unable to claim registration on either a colonial or a foreign qualification, unless he got it in course of a continuous absence from the United Kingdom of not less than five years; and that, in general, both a foreigner and a colonist (as to whose domicile there will usually be no room for doubt) will have no difficulty in claiming on either.

Provision is made (Section 15) for the entry in the Register of the qualifications possessed by persons registered as colonial or foreign practitioners. Provision is made also (Section 16—another transitory provision) for the registration of foreign degrees in medicine possessed by practitioners registered on British or Irish qualifications which have been obtained after proper examination, and prior to the passing of the Act.

As to previous proposals or suggestions on the subject of the Act, the clause relating to foreign and colonial practitioners contained in Lord Ripon's Bill of 1870 differed widely from the provisions now enacted, since it would have confined registration to persons over forty years of age, and who had been not less than ten years in practice. The General Council had previously (July, 1869) expressed itself in favour of provision being made to enable it, by special orders, to dispense with such conditions of the Medical Acts and such of the regulations made under them as it should think fit, where foreign or colonial practitioners applied for registration. A resolution altogether unfavourable to the registration of foreign degrees—proceeding upon a communication from graduates holding such degrees, themselves apparently already upon the Register—was subsequently, in 1876, arrived at by the General Council. A close approach, however, to what has now been enacted was made by the President of the General Council in 1879 in a communication written for the Select Committee of that year. There was at that time in France an agitation for the exclusion of foreign practitioners from the privilege of practising in France. The President thought that, if a joint committee of foreign and English representatives could be got to consider the matter, "it might be possible to bring about reciprocal action which would be just and beneficial to all parties"; and which "would tend to secure a wise and uniform standard of medical education, whether practical or scientific, in all civilised communities."

*** The above article was unavoidably omitted from our last issue.

OUTBREAK OF ANTHRAX IN CATTLE, AND FIVE MEN INFECTED.

By JAMES A. FRASER, L.R.C.P. Lond., M.R.C.S.

THINKING that a history of the following outbreak of anthrax might prove of interest to many readers of THE LANCET, I send a short sketch of it.

On June 6th a cow was taken suddenly ill, the cause of the illness being attributed to the excessive heat; it was slaughtered, and the meat, not being condemned, was disposed of. No farther case occurred until July 1st, when a second cow was taken ill suddenly and died. Splenic fever was diagnosed, and found correct on post-mortem examination. On the 6th two beasts, a cow and pony, were affected and died, splenic fever in both being found to be the cause of death. On the 11th a sow was taken ill, and on inspection was found to be enormously swollen. This sow was fed on the offal of the cow that died on July 6th. On the 12th a fourth cow died of splenic fever. The entrails of this last cow were buried in a dung-heap situated at the top of an incline in the pasture. All the above beasts were pastured in the one field, which had never had a case of splenic fever in it before June 6th, a stagnant pond being supposed to be the source of infection.

On July 24th I was informed that Henry P——, by occupation an odd job man about the market, and who was in the habit of wheeling offal from the slaughterers, had been admitted into the union infirmary, the time of admission being 4.30 P.M. He was seen by my assistant, Dr. James Lawson, the note on his admission card being "mitral disease and pneumonia." His condition was as follows:—Cyanosis of face, ears, hands, and arms up to elbows, and of feet and legs up to knees; breathing very laboured, 40 per minute; dulness over base of left chest at back, and slightly over base of right lung; loud râles, especially in left chest; heart sounds rapid and faint, and covered by the chest râles; radial pulse not to be felt; perspiration standing in beads on the face. The patient spoke once, and said that he was infected while helping to dress a cow. The date of such dressing could not be ascertained, as he became comatose, and died at 8.30 P.M.

A post-mortem examination was made forty hours after death, the following being a copy of the report:—Skin of face jaundiced; lips livid; cyanosis marked; hypostatic congestion of skin of body; an ulcer at junction of upper and middle thirds of right tibia; no other skin lesion found. The pericardium contained an ounce and a half of blood-stained serum. Pleura on right side non-adherent; on left side, new and old adhesions present, very firmly bound down at the base, the lung tearing on attempting to remove it. Right lung congested; left lung congested and rotten at the base; no sign of abscess anywhere; lung floating. Heart: Right side contained clot; both valves normal. Left side, wall hypertrophied; full of coagulated blood, which was soft, not firm; the lining membrane much stained. Aortic valves would not admit the finger; patches of atheroma were present on the aorta; patches of granulation on ventricular surface of the valves. Mitral valve puckered and incompetent, and granulations on the ventricular surface; admitted two fingers. The liver weighed 3 lb. 5 oz.; it was healthy, but congested. The spleen was not enlarged, but was congested and broke down easily. Kidneys: Weight, 11¾ oz.; congested and tough. Intestines very congested in patches, corresponding to the long axis of intestine; the congestion of the intestines was most marked towards the ileo-cæcal valve; the glands of Peyer showed nothing abnormal; solitary glands enlarged; mesentery much congested. Brain: Vessels full; on section the vessels stood out full of clot; ventricles empty. The pleural, pericardial, peritoneal, and meningeal spaces contained blood-stained serum. On examining the blood, dried on cover glasses, stained with gentian violet, and mounted in balsam, great numbers of anthrax bacilli, some very long, were found in every field. On examining scrapings of the spleen prepared in the same way, more numerous but shorter anthrax bacilli were present.

On making inquiry, Mr. Mackenzie, under whose care the above patient was before admission into the union, has furnished me with the following list of cases which have been under his care:—

1. G——. Summoned to attend fifteen hours after infection; found patient with pneumonia and hæmoptysis; two malignant pustules on right forearm. Died four hours after seeing him.

2. S——. Large malignant pustule on right cheek; great swelling; free application of absolute phenol; large slough; no secondary mischief. Recovery in three weeks and a few days.

3. K——. Malignant pustule on left brow, treated with absolute phenol. Recovery in a fortnight.

4. M——. Questionable pustule on hand; seen early; arm œdematous and inflamed. Used absolute phenol. Recovery in ten days.

It will thus be seen that Mr. Mackenzie had five cases under his care, three of which were recovering.

The fact of anthrax not coming under the Contagious

Diseases of Cattle Act prevents the local inspector from proclaiming the pasture on which the outbreak occurred as an infected area, so that other beasts may be turned down on it and so become infected. If the meat is not condemned it may become a source of infection to human beings. The slaughterers, not being aware of the danger attending the skinning and cleaning of such infected cattle, are very careless, and run great risks—e.g., eating pieces of the suet, holding the skinning knives in their teeth, &c.; and, last but not least, the offal not being burned, but buried, proved to be a fresh source of infection, as may be seen by what follows.

On July 26th, the veterinary surgeon (Mr. Gray) was called up early in the morning to see a horse which had been taken ill and died, the symptoms being great thirst, purging, and staggering. On post-mortem examination splenic fever was found to have been the cause of death. Four hours afterwards he was called to the same field to a pony with the same symptoms; this also died; cause of death splenic fever. These two beasts had been feeding round the manure heap, in which the offal from the cow which died on July 12th had been buried. I was given specimens of the blood of the horse and pony, the buffy coat having already formed. On drying on covered glasses, staining with methylene blue, and mounting in balsam, very numerous and well-marked anthrax bacilli were found. I have shown the above specimens of human blood and spleen scrapings, and of the blood of the horse and pony, to Mr. Davies-Colley and Mr. Jacobson of Guy's Hospital, and both declare them to be doubtless specimens of anthrax bacilli.

THE AFGHAN BOUNDARY COMMISSION.

THE Medical Report of the hospital service connected with the escort which accompanied the Afghan Boundary Commission in 1884–85, by Surgeon-Major Charles, of the Indian Medical Service, contains some very interesting information regarding the countries through which it marched, and the health of the men under the arduous work they had to perform. The escort, consisting of 7 officers, 455 fighting men and 286 followers, a half field hospital with 1 medical officer, 3 subordinates, 10 medical establishments, and 56 followers, left Sirimungli, near Quetta, on Sept. 22nd, 1884, and reached their winter quarters at Bala Murghab on Dec. 13th. Here they remained in a standing camp till Feb. 15th, when they marched to Gulran in very severe weather, arriving at their destination on Feb. 23rd. On April 3rd and 4th they moved in two parties across the Ao Safed Pass to Tirpul, near Khusan. The second party encountered a sudden storm of great violence in the Pass, and lost by it twenty-four men, with many mules, camels, and some horses. "The men of this division continued to arrive at Tirpul in driblets for some days. During this time and for long after, the half field hospital had a sufficiency of work, and with most excellent results to the storm-tossed sick." After the recall of Sir P. Lumsden in May, the escort, divided into two parties, was stationed in or near the Herat Valley, occupying various camps till the end of September, when the strength was reduced, and a return party formed of 254 fighting men and about 220 followers. These started from Mamisak on Dec. 1st, and reached Sirimungli on Jan. 22nd, 1886, having been one year and four months employed on this service. The total distance marched during the expedition was 2316 miles. The rate of marching on the upward journey to Bala Murghab averaged, exclusive of halts, eighteen miles a day, and on the return from Mamisak, fifteen and a half miles. On the way up, the marching was done at night; on the way down, by day; and the health of the men was decidedly better during the latter, but this may have been due, in a considerable degree, to better arrangements, better water, and the men being more inured to marching. On this service the men were exposed to great vicissitudes of temperature, the thermometer in 1885 having ranged between zero in January and 104° in July. "The extremes of temperature are at times very great, as many as 70° or 80° F. between day and night temperatures." During the winter at Bala Murghab the men were lodged in Kibitkas, and every care was taken to protect them from the damp. Dr. Charles says that "in the coldest weather an equable temperature can be maintained in them. ..... Looking back at the time spent in Kibitkas, properly prepared as I have noted, I have no hesitation in saying that they served their ends in a way that could not be surpassed, and I attribute to them, in a measure, the small mortality among the sick treated in hospital. Kibitkas can be made cool in hot weather, and warm in cold weather; and the ventilation at all times, with care, can be rendered excellent." The information given respecting the health of the men is unsatisfactory—probably unavoidably so, owing to the frequent moves and to the party being so often broken up; but there is no statement of the mortality, except that already noted as arising from the storm in the Ao Safed Pass, and the admissions into hospital are only recorded for broken periods, while the principle on which the return of out-patients has been made up is not stated. We can, therefore, only draw some general conclusions as to the diseases from which the troops suffered. On the march up there seems to have been a considerable prevalence of dysentery among both the fighting men and the followers, but this apparently ceased after reaching Bala Murghab. Surgical injuries and diseases, and fevers, were the chief causes of admission into hospital after that date. In the first two months of 1885 cases of bronchial catarrh were very frequent among the out-patients of both classes, and next to these boils and ulcers, and dyspepsia. In June, July, and August a considerable number of cases of conjunctivitis occurred, attributed chiefly to the dust and sand. It is worthy of remark that, notwithstanding the very low temperature of the winter, there were scarcely any cases of frost-bite till after the march across the Ao Safed Pass. This immunity was probably due to the housing of the men in the kibitkas and to providing them with a liberal supply of warm clothing.

Among the diseases most prevalent in the civil population of the country, Dr. Charles specially notes paroxysmal and typhoid fevers, rheumatism, dyspepsia, bronchial catarrh, syphilis, scurvy, and worms. Cholera is said to have been very rife in the Herat Valley in the past, but it did not appear among the men of the escort or the followers. No cases of sunstroke occurred among the men, and although many of them were bitten by camp and pariah dogs, none of them suffered from rabies. Some interesting notes are given of cases, and of the remedies found most efficient in their treatment. We would merely notice the internal use of hot water in ague and remittent fever, instead of the usual diaphoretics. Dr. Charles says that he never found it fail to give relief. "Pain would vanish, giving place to a feeling of ease; thirst would be no longer felt; the burning skin would be suffused in a gentle sweat; the aching head, with heavy eyelids, would sink to rest in a calm and placid slumber." The water must be hot, not tepid—"so hot that it can just be swallowed without scalding, and no more,"—and is to be followed by quinine.

There are, we think, some valuable practical lessons to be derived from the experience gained on this expedition. We would note the importance, from a health point of view, of marching the troops by day instead of night, but this, of course, would not be applicable to the hot summer months; the advantage of housing the men in winter in a manner adequate to protect them from the excessive cold, and of providing them with sufficient warm clothing; the propriety of avoiding the occupation of old buildings, such as the robats and forts, as quarters for the men, which at one time it was proposed to do, but which was abandoned on the recommendation of the medical officer. Dr. Charles, in some notes on the transport of the sick, has pointed out the disadvantages of the Moseley Khajawa, as supplied to the expedition, and recommends the Herat Khajawa, as being much better suited, especially for winter use, in such a climate. He has also called attention to the necessity of an inspection, by a medical officer, of the followers who are to accompany the troops on service, as men unfit for field service or the inclemency of a severe climate are often taken, and prove a serious encumbrance to the force. He also strongly advises the erection of urinals for standing camps. "No urinals were used in the standing camps (in spite of remonstrances), so that in a short time the top soil became saturated with urine and a breeding-place for flies and noxious effluvia, &c."

AT the Newcastle-under-Lyme Police-court on the 5th inst., a Macclesfield dealer was fined £10 for exposing for sale a quantity of beef which was unfit for human food.

CALENDAR OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE Annual Calendar has just been published by the Council of the College. From it we ascertain the following facts:—

It appears that there are 1124 Fellows on the roll of the College, of whom 639 obtained the Fellowship by examination, 7 were elected as Members of twenty years' standing under Section 5 of Charter 15 Vict., and 2 are *ad eundem* Fellows. There are 17,040 Members, and 957 Licentiates in Midwifery (the examination for this licence having been suspended for the last eleven years). The Licentiates in Dental Surgery number 590.

The examiners in Elementary Anatomy and Physiology, appointed in conjunction with the Royal College of Physicians, under the scheme for an Examining Board in England, are elected annually. There have been four examinations during the past year, 716 candidates presenting themselves, of whom 474 passed in both subjects, 77 in Elementary Anatomy, and 96 in Elementary Physiology; 55 candidates were referred in both subjects; 63 were referred in Elementary Anatomy, and 63 in Elementary Physiology. The fees received from candidates for this examination amount to £3581 16*s.* 3*d.*, the Examiners receiving in fees £506 15*s.*

The examiners in Anatomy and Physiology appointed in conjunction with the Royal College of Physicians, under the scheme for an Examining Board in England are elected annually. They have conducted the Primary Examinations for the diploma of Member under the old regulations, as well as the Second Examination of the Examining Board, and have held during the year four examinations, at which 1079 candidates presented themselves, of whom 262 passed in both subjects, 173 in Anatomy, and 246 in Physiology; 97 were referred in both subjects, 240 in Anatomy, and 214 in Physiology. The fees received from the candidates for this examination amount to £4363 16*s.*; the examiners receiving £2259.

The Board of Examiners in Anatomy and Physiology for the diploma of Fellow consists of nine members annually elected by the Council from the Fellows of the College, and has held during the past collegiate year two examinations, 117 candidates presenting themselves, of whom 62 passed and 55 were referred. The fees received from this examination amount to £829 10*s.*; the Board receiving in fees £526 10*s.*

The Court of Examiners consists of ten members, elected by the Council from the Fellows of the College, all of whom, however, are members of the Council, except Dr. Humphry, Mr. John Langton, and Mr. T. Pickering Pick. During the year the Court has held two examinations for the Fellowship and four for the Membership. At the former there were 51 candidates, 28 of whom passed, 19 being referred for one year and 4 for six months. For the Membership there were 1048 candidates, 319 of whom obtained their diplomas, and 270 passed in Surgery only; 103 were referred for three months, 320 for six months, 14 for nine months, and 22 for one year. The fees paid by candidates amounted to £12,737 16*s.*; the fees paid to the Court of Examiners amounting to £6027 7*s.*

The Board of Examiners in Dental Surgery has held two meetings for the examination of twenty-eight candidates, twenty-one of whom obtained their diplomas. The fees paid by them amounted to £220 10*s.*, of which the Board received £88 4*s.*

The income of the College from all sources during the past year amounted to £40,742 11*s.* 5*d.*, derived principally, as already shown, from fees paid by candidates for the diplomas of the College—viz., £21,753 8*s.* 3*d.* Rents from chambers adjoining the College produce £1520 0*s.* 6*d.*; dividends on stock, £1154 19*s.* 2*d.*; from members of the Council and Court of Examiners on their election, £76 6*s.*; from sale of stock, £12,500 7*s.* 1*d.*; from trust funds and sale of Calendar and Synopsis, £273 6*s.* The expenditure for the year amounted to £40,137 5*s.* 7*d.*, the largest item being £12,816 7*s.* 7*d.* for purchase of house, No. 44, Lincoln's-inn-fields. The next largest amount appears in fees paid to examiners—viz., £9446 6*s.* Salaries, wages, and pensions for officers and servants of the College in the three departments—library, museum, and office—amount to £4645 14*s.* 6*d.* Taxes, rates, diploma stamps, and insurance absorbed the sum of £1670 1*s.* 9*d.* Half expenses for new Examination Hall, £5978 5*s.* 5*d.* Under miscellaneous items, extraordinary expenses, alterations and repairs, the sum of about £4000 appears to have been expended.

THE PHARMACEUTICAL SOCIETY.

THE introductory address at the commencement of the forty-fifth session of the School of Pharmacy was delivered on the 6th inst., by Sir Henry W. Acland, Regius Professor of Medicine in the University of Oxford, and President of the General Medical Council. After alluding briefly to the future of Science, he spoke of some of the medical agents contained in the Pharmacopœia of 1651—silkworms, toads, swallows, ants, &c.; and remarked that it was surprising how so monstrous a list could have been authoritatively issued after Linacre had lived and taught in that great college which he founded, and which was destined to shed lustre on the history and character of medicine. Sir Henry next spoke of the step about to be taken by the Pharmaceutical Society—viz., the establishment of a laboratory for special research into the exact chemical constitution of drugs and alleged remedies, with a view to the precise fixing of the constitution of alkaloids of acknowledged or hypothetical value, and to the discovering, and generally the guaranteeing to the experimental therapeutist and the physiological inquirer, absolutely pure bodies of known chemical constitution, whether existing in commerce or not. Sir Henry then reviewed the progress of the Pharmacopœia, and advocated the publication of a small volume which would lay down, by international consent, the mode of obtaining with certainty the best remedies made in the best manner, with rules of how to preserve them in all climates, and how readily to distinguish them. He regretted that no steps had been taken to obtain representatives from India, from the Dominion of Canada, and from Australasia to co-operate with England in researches connected with the Pharmacopœia, this being especially desirable owing to the admission after the present year of colonial and foreign practitioners to the Medical Register. The conclusion of the address was devoted to an exhortation to diligence, cleanliness, order, and exactitude on the part of the students in their studies, and in their future career as dispensers.

HOSPITAL REUNIONS.

MIDDLESEX HOSPITAL MEDICAL SCHOOL.

AT the distribution of prizes to the successful students of the Middlesex Hospital, which took place on Monday last, after Dr. Biss's introductory lecture the chair was taken by Dr. Headlam Greenhow, F.R.S., who was formerly so long attached to the hospital. The Dean, Mr. Pearce Gould, in his report, stated that plans for an extension of the school buildings had been prepared, and that the erection of these buildings and those of the proposed residential college would shortly commence. Dr. Greenhow addressed a few words to the students, and a cordial vote of thanks to him was passed with acclamation. The customary annual dinner took place at the Holborn Restaurant in the evening. The chair was taken by Mr. Andrew Clark, F.R.C.S., who has held the office of Dean for ten years. The gathering was an unusually large one, and the post-prandial speaking was lightened by most excellent singing and music by Mr. Ganz, Dr. Pringle, Mr. Critchett, Mr. Hepburn, and Mr. Fulkerson, the proceedings terminating at a late hour with the whole company joining in "Auld Lang Syne." The toasts included "The Middlesex Hospital Medical School," given by the chairman and responded to by Mr. Hulke, F.R.S.; "The Middlesex Hospital," proposed by Dr. C. West and acknowledged by Major Ross, M.P., chairman of the Weekly Board; "The Past and Present Students," given by Mr. T. W. Nunn, and replied to by Sir Oscar Clayton on behalf of the past students, and Mr. W. G. Nash on behalf of the present students; the health of the "Orator of the Day" was proposed by Dr. Edis and acknowledged by Dr. Biss; that of "The Chairman" was given by Mr. Morris; and the toast of "The Visitors," which was

Digitized by Google

given from the chair, was responded to by Mr. Burdett, who, in concluding, proposed the health of the new Dean, Mr. Pearce Gould. The gathering was acknowledged by all to have been a great success, and it was marked by much cordiality and heartiness.

UNIVERSITY COLLEGE.

THE annual dinner of the old and present students of the Faculty of Medicine took place at the Freemasons' Tavern on Oct. 4th, under the presidency of Sir William Roberts, Professor of Medicine in the Victoria University, Fellow of University College. The chairman was supported on his right by Dr. George Buchanan, and on his left by Professor Michael Foster. Among those present were—Professor Russell Reynolds, Professor Burdon Sanderson, Dr. Henry Maudsley, Dr. William Wood, Dr. Morris (Spalding), Mr. Waggett, Mr. Bluett (Chesterfield), Mr. Humphreys (Shrewsbury), Mr. Kiallmark, Dr. Allen (Hastings), Dr. Snow (Bournemouth), Dr. Price (Cardiff), Mr. William Gill, Mr. Bernard Roth, Mr. Embleton (Bournemouth), Dr. C. Beevor, Mr. Hodson (Brighton), Mr. Peter Cooper (Blackheath), Mr. Buckston Browne, Dr. Percy Gabb (Guildford), Dr. Amand Routh, Mr. W. Rigden, Mr. J. Prince Bartlett, Dr. Magrath (East Grinstead), Mr. Foster Macgeah, Mr. Harvey (Bromley), Mr. Twynam (Sydney, N.S.W.), Dr. Easmon (Gold Coast), Dr. Pasteur, Mr. Campbell Williams, Mr. Drew (Oxford), Dr. Lewers (London Hospital), Mr. Williams-Freeman (Portsmouth), Mr. Stewart Norman (Havant), Mr. Swift, Mr. Peter Giles (Hereford), Mr. W. A. Meredith, Dr. Cock, Mr. Bowreman Jessett, Mr. H. A. Powell (Beckenham), Mr. Copley (Wisbech), Mr. Fraser Stokes, Mr. Frankish, Dr. Penrose, and others. The present members of the hospital staff and the professors of the Medical Faculty of the College were all present, with very few exceptions; and these, with a large contingent of students, made up a company of about 100. There was some excellent speaking from the chair, and from Dr. Buchanan, Dr. Michael Foster, Dr. Burdon Sanderson, Dr. Wilson Fox, and Dr. Graily Hewitt; and the proceedings were enlivened by some first-rate singing by Dr. F. T. Roberts, Dr. Beevor, Mr. Campbell Williams, and Mr. Copley. This very pleasant reunion of old friends was brought to a close at about 11 o'clock.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.

After the delivery of the introductory address on the 4th inst., the Dean read his annual report for the year, and drew attention to the fact that all the first-year's students who came under the new regulations had passed the examination recently instituted by the conjoint Board of the Royal Colleges of Physicians and Surgeons in Anatomy and Physiology at the end of the first winter session. The prizes gained during the past year were given away by the Venerable Archdeacon Farrar, who afterwards addressed some eloquent remarks to the students on the connexion between the medical profession and the clerical profession and literature, giving numerous illustrative examples, and he concluded by exhorting his hearers to respect humanity and to respect themselves. The annual dinner of the staff and past and present students was held in the evening at the Holborn Restaurant. The Hon. Mr. Justice Wills was in the chair, and among the guests were Col. Duncan, R.A., M.P., Col. Sparkes, Major Davis, the Rev. T. S. Echalaz, &c.

ST. THOMAS'S HOSPITAL.

A CROWDED audience of students and their friends assembled in the operating theatre to listen to the introductory address of Dr. Bristowe, on Friday last. Nearly all the members of the hospital staff and lecturers were present, and several students from other hospitals. The address, which we publish this week, was listened to with great attention, abounding, as it did, in sketches of bygone members of the staff who helped to make it famous, and on its completion the lecturer was greeted with loud applause. In the evening the annual dinner took place in the Governor's Hall, at which there was a good attendance. Mr. C. W. Chaldecott, of Dorking, occupied the chair, a most pleasant evening being spent. The chairman proposed the usual toasts; Dr. Stone, in a witty speech, "The Health of the Visitors," which was replied to by Professor Wm. Thomson and Dr. Savage. Alderman Stone (treasurer) replied for the hospital. Dr. Bristowe, F.R.S., proposed "The Chairman," and Mr. J. R. Lunn, in the absence of Mr. John Simon, C.B., F.R.S., "The Medical School," to which Dr. Ord replied, referring to its increased prosperity, and the additional accommodation recently provided in the anatomical and other departments, and to changes in the teaching. Mr. Le Gros Clark, Mr. John Croft, Dr. Alfred Carpenter, and Dr. H. W. G. Mackenzie also spoke.

GUY'S HOSPITAL.

PUPILS' PHYSICAL SOCIETY.

IN order to mark the beginning of the session, the Pupils' Physical Society held their first meeting on the evening of October 4th, in the anatomical theatre, which was completely filled, there being only standing room for several members both past and present. The treasurer and many members of the staff attended. Dr. Wilks, LL.D., F.R.S., was in the chair, and in a short opening address he first referred to the great loss the hospital had sustained in the death of Dr. Moxon, alluding especially to the manner in which he had by his untiring industry, energy, and skill enriched the pathological department by the addition to it of the well-known and beautiful series of water-colour drawings of pathological specimens which now hang on the walls of the post-mortem theatre. Dr. Wilks pointed out that, although the profession sustained from time to time great individual losses, yet the profession itself went on, and we must by hard work keep ourselves ever ready to fill up the gaps in the ranks. After congratulating the new students upon having entered a school which he so loved, of which he thought so highly, and at which the opportunities for work in all the departments were so numerous, the speaker went on to tell the students of the antiquity of the Physical Society of Guy's, which is the oldest medical society in London. He then mentioned the distinguished men, such as Dr. Jenner, who had spoken from the same theatre as that in which the Society now holds its meetings, and read extracts from the address delivered on similar occasions to the present, many years ago, by such men as Dr. Babington and Mr. Allen. Finally, after telling the new students that by joining Guy's they had taken upon themselves an obligation to work for the credit and fair name of the school to which they were attached, he called upon the reader of the paper of the evening to begin. Dr. Ryle, whose paper was entitled "The Rise and Progress of Medicine," gave a most interesting and full account of our advance from the time of Hippocrates downwards, showing that that father of medical art and science had a most wonderful insight into many of the problems of his craft, and that often there was an exactitude in his observations which it would be well if we nowadays were sometimes to imitate. Dr. Ryle proceeded to read several very instructive reports of Hippocrates' cases, making comments upon them in passing. He then touched upon all the epoch-marking periods of medicine, alluding especially, first of all, to Galen, who had done as much to retard medicine as to advance it by promulgating with his great authority many ill-founded theories. After alluding to Harvey and some of the later masters in medicine, Dr. Ryle concluded his paper. A brisk debate, carried on by the past and present members of the society, followed, and the reader of the paper replied. A vote of thanks to the treasurer was proposed by Mr. Lund, the senior house-surgeon, and seconded by Mr. Beard, the junior house-surgeon. The Treasurer, in replying, alluded to the great loss which the governors felt in the death of Dr. Moxon. He said it was a great pleasure to come to these meetings, and that he never failed to hear something which gave him material for deep thought for some time to come. Mr. E. W. Goodall, M.B., the senior house-physician, proposed, and Mr. Beard seconded, a vote of thanks to Dr. Wilks for presiding. In the course of his remarks Mr. Goodall said what a pleasure it was to the students that Dr. Wilks, although consulting physician to the hospital, still came down often in the afternoon and gave them the benefit of his great knowledge. After a brief reply from Dr. Wilks the meeting broke up. During the evening the museums were lit up, so that the past students had an opportunity of refreshing their memories by again looking at the famous specimens and wax models for which the Guy's museum is so well known. Many microscope specimens were exhibited, and all who attended appeared to have had a very pleasant evening.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Islington.—The population of St. Mary, Islington, may be taken at about 318,638, and in this the death-rate was 16·7 for 1885; this being the smallest death-rate on record. The birth-rate was 30·3 per 1000. Amongst the zymotic diseases small-pox was severely epidemic during the first six months of the year, measles was fatally epidemic, and the deaths from diphtheria, which had been rapidly increasing for some years past, amounted to 138. A large number of the sick were removed to the Metropolitan Asylums Board hospitals and to the Highgate Small-pox Hospital. Of the small-pox cases 42·9 per cent. died amongst the unvaccinated, whereas the rate was only 13·7 per cent. amongst the vaccinated. During the year the Vestry destroyed 421 articles which were infected, including 125 beds, and all these were replaced at the cost of the public, the amount thus spent reaching close upon £300. Dr. Meymott Tidy includes in his report tables as to the analysis of the New River Company's water, and as to the amount used per house; details are also given as to the licensing of slaughter-houses and cow-houses, as to summonses taken out under the Sanitary Acts, the renovation of certain of the dwellings of the poor, and action under the Sale of Food and Drugs Act. Having regard to the exigencies of public opinion and to the freer exercise of the right of complaint by the inhabitants, a large extension in the way of sanitary inspection became necessary in the parish, and besides other modifications four additional inspectors have been appointed, and regulations have been made defining more clearly the several duties of the inspectorial staff.

Surbiton Urban District.—During 1885 the death-rate for Surbiton was only 9·7 per 1000, and two deaths each from whooping-cough and diphtheria were the only ones due to zymotic diseases. The diphtheria cases are referred to as sporadic only. There is no description of the sanitary circumstances existing in the district, and apart from a list of nuisances dealt with, which is supplied by the inspector of nuisances, and a statement that the town is still without any hospital for infectious diseases, the wants of the district are not referred to. Perhaps, with a repeated low death-rate, the sanitary wants of the district are but few.

Huddersfield Urban District.—The general death-rate from all causes in 1885 was 20·1 per 1000 in Huddersfield, and that from the seven principal zymotic diseases 1·4, this latter being one of the lowest rates on record. In his report, Dr. Cameron draws attention to an excessive amount of death from "consumption" in the borough, and in this connexion he refers to density of population as facilitating the spread of a disease now admitted to be communicable. Thus, overcrowding becomes, from the point of view of this mortality, a vital one in the matter of public health, and anything tending to the undue aggregation of people, especially as regards their sleeping accommodation, needs to be specially dealt with where any tendency to excessive phthisis mortality is met with. During the year the authority's hospital has been in general use, and at one time the amount of accommodation was found to be insufficient. The site is, unfortunately, a restricted one for such a borough, although some of the accommodation it provides is very good. Scarlet fever was prevalent, and its spread is stated to have been in part due to unnotified cases. No such thing as intentional withholding of certificates on the part of medical men is suggested, but cases in which there was doubt as to diagnosis led to some difficulty in this respect. Where the notification was from the householder alone, there was tardiness, and Dr. Cameron thinks that some parents preferred wilfully to remain ignorant of the fact that their children had scarlet fever, so as to avoid the notification. But there has been no increasing antipathy to compulsory notification, and on the whole the Act is said to work well.

Wallasey Urban District.—As in so many other districts, the death-rate for Wallasey during 1885 was exceptionally low, the rate being 14·9 per 1000; the infantile death-rate and that from zymotic diseases were also low. In connexion with the general sanitary administration of the district, eighty soil-pipes were ventilated, several hundred drain-pipes were disconnected, houses were supplied with proper water-supply, and a large number of other improvements were effected. In 1884 a thorough systematic inspection of the district was made, and, as is usually the case, this was the forerunner of a large amount of detailed sanitary work, which must necessarily go to improve the healthiness of the town. Full details of this excellent work are given by Dr. Craigmile in the report under consideration.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5539 births and 3592 deaths were registered during the week ending Oct. 2nd. The annual death-rate in these towns, which had been equal to 22·6 and 21·0 per 1000 in the preceding two weeks, further declined last week to 20·0. During the thirteen weeks ending last Saturday the death-rate in these towns averaged 20·4 per 1000, and was 0·8 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 15·2 in Brighton, 16·9 in Bradford, 17·0 in London, and 18·2 in Derby. The rates in the other towns ranged upwards to 27·7 in Leeds, 27·7 in Bolton, 29·2 in Manchester, and 29·4 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 1202, 1133, and 933 in the preceding three weeks, further declined last week to 746; they included 532 from diarrhœa, 61 from scarlet fever, 59 from "fever" (principally enteric), 33 from diphtheria, 32 from measles, 29 from whooping-cough, and not one from small-pox. The lowest death-rates from these zymotic diseases were recorded last week in London, Huddersfield, and Plymouth; and the highest in Norwich, Hull, Wolverhampton, and Preston. Diarrhœa caused the highest death-rates in Wolverhampton, Hull, and Preston; the mean rate in the twenty-eight towns being considerably above the average for the last week in September. The mortality from "fever" was greatest in Portsmouth, Bolton, Norwich, and Plymouth; from scarlet fever in Liverpool, Bristol, and Salford; from whooping-cough in Norwich and Wolverhampton; and from measles in Halifax. The 33 deaths from diphtheria included 20 in London, 4 in Liverpool, 2 in Leeds, and 2 in Cardiff. Small-pox caused no death in London and its outer ring, or in the twenty-seven large provincial towns; and only one small-pox case was under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had been 110, 168, and 154 in the preceding three weeks, further rose last week to 187, but were 35 below the corrected average. The causes of 87, or 2·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Blackburn, Wolverhampton, and Halifax. The largest proportions of uncertified deaths were registered in Huddersfield, Manchester, Oldham, and Nottingham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·6, 18·8, and 16·8 per 1000 in the preceding three weeks rose again to 18·3 in the week ending Oct. 2nd; this rate was 2·3 below the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 9·8 and 13·0 in Perth and Paisley, to 19·9 in Aberdeen and 21·7 in Glasgow. The 452 deaths in the eight towns last week showed an increase of 37 upon the number in the previous week, and included 34 which were referred to diarrhœa, 14 to whooping-cough, 8 to scarlet fever, 4 to "fever" (typhus, enteric, or simple), 2 to diphtheria, 1 to measles, and not one to small-pox; in all, 63 deaths resulted from these principal zymotic diseases, against 93, 73, and 78 in the previous three weeks. These 63 deaths were equal to an annual rate of 2·6 per 1000, which was 1·7 below the mean rate from the same diseases in the twenty-eight English towns. The deaths referred to diarrhœa, which had been 57, 45, and 43 in the preceding three weeks, further declined last week to 34, of which 15 occurred in Glasgow, 6 in Dundee, 4 in Edinburgh, 4 in Aberdeen, and

Digitized by Google

3 in Leith. The mean annual death-rate from diarrhœa in the Scotch towns last week was again considerably below that which prevailed in the large English towns. The fatal cases of whooping-cough, which had been 20, 11, and 18 in the previous three weeks, declined again to 14 last week, and included 10 in Glasgow and 3 in Edinburgh. The 8 deaths from scarlet fever, of which 7 occurred in Glasgow, were within one of the number in the preceding week. The 4 deaths referred to "fever" were below the average for the season, and corresponded with the number in the previous week. The fatal cases of diphtheria and measles were also below the average. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 65 in each of the preceding two weeks, were 67 last week, and exceeded the number in the corresponding week of last year by 9. The causes of 66, or nearly 15 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 27·5 and 24·7 per 1000 in the preceding two weeks, further declined to 22·8 in the week ending Oct. 2nd. During the thirteen weeks of the quarter ending last Saturday the death-rate in the city averaged 22·1; the mean rate during the same period was 18·7 in London and 17·5 in Edinburgh. The 154 deaths in Dublin last week showed a decline of 13 from the number in the previous week, and included 23 which were referred to diarrhœa, 8 to scarlet fever, 2 to "fever," and not one either to small-pox, measles, diphtheria, or whooping-cough. Thus 33 deaths resulted from the principal zymotic diseases, against 39 and 30 in the preceding two weeks; they were equal to an annual rate of 4·9 per 1000, the rates from the same diseases last week being 2·4 in London and 1·6 in Edinburgh. The fatal cases of diarrhœa, which had been 29 and 25 in the previous two weeks, further declined last week to 23. The deaths referred to scarlet fever, which in the preceding two weeks had been 2 and 3, rose last week to 8, a higher number than in any week since the middle of last year. Five inquest cases and 4 deaths from violence were registered; and 38, or nearly one-fourth of the deaths, were recorded in public institutions. The deaths of infants showed a further decline from those returned in recent weeks, while those of elderly persons showed a slight excess. The causes of 23, or nearly 15 per cent., of the deaths registered during the week were not certified.

Correspondence.

"Audi alteram partem."

DR. GLOVER'S CANDIDATURE AND THE BIRMINGHAM COMMITTEE.

To the Editor of THE LANCET.

SIR,—The letter of Dr. Strange, the chairman of the Birmingham Committee, which you published on Oct. 2nd, and your own leader of that date, informed the profession that from regard to my place in the test-ballot by that committee they have now invited me to be their third candidate. The profession will naturally expect to hear the decision of my committee and my own opinion in regard to that invitation. I will ask you, with this view, kindly to publish my letter to Dr. Strange (which contains the resolution of my committee) in reply to his overtures, acting as chairman. In announcing this resolution, I wish to acknowledge with gratitude the courtesy of Dr. Strange and his colleagues. I am well aware of the value of organisation, but, at all hazards, we must preserve freedom.

Believe me, Sir, your obedient servant,

Highbury-place, N., Oct. 5th, 1886. JAMES GREY GLOVER.

"25, Highbury-place, Oct. 2nd, 1886.

"DEAR DR. STRANGE,—I lose no time in informing you of the result of the consideration by my committee of the proposal that I should stand as the third candidate of your nomination for the office of direct representative of the profession in the General Medical Council. The resolution of my committee is as follows:—

"'That this committee, having considered the letters written by Dr. Strange and Mr. Ker on behalf of the Birmingham Committee, in which Dr. Glover is informed that he has been adopted as the third candidate on their list, and in which, further, they express the desire that this committee, formed (two months since) to promote Dr. Glover's candidature, should amalgamate with the Birmingham Committee to promote the election of Messrs. Wheelhouse, Foster, and Glover—the three candidates now selected by the Birmingham committee as the most suitable to represent the profession in the General Medical Council,—do hereby resolve that the best thanks of the committee be given to the members of the Birmingham Committee for their proffered aid in advancing the election of Dr. Glover, and for the way in which they have mentioned his suitability for the post, as well as his claims on the profession; but, as many members of his committee have already promised their support to other candidates, and many other members decline to have their freedom of selection curtailed, it is impossible for the two committees to amalgamate to fulfil the objects of the Birmingham Committee.'

"I need not say how gratifying it is to me to stand well in the estimation of so many members of your committee; nor what a pleasure it would have been to me to co-operate with you, and to be associated in a joint candidature with Mr. Wheelhouse and Sir Walter Foster. But I am bound to say that I heartily concur with my committee. What we want above everything is to aid the free and spontaneous expression of the views and preferences of the medical profession, and to avoid mechanical ways of tying candidates and voters together. I shall still prize the support of the individual members of your committee, and trust to your kindness and courtesy, of which I have had not a little proof, to believe that, in electing to stand as an independent candidate, I am only doing what I feel to be right in the interest of the profession, which we all have at heart.

"Believe me, dear Dr. Strange, yours very truly,

——— "JAMES GREY GLOVER."

To the Editor of THE LANCET.

SIR,—I must say I am somewhat surprised to see how few of the candidates are what may be called typical general practitioners—i.e., men who hold union and club appointments, and have to face practice of all kinds and amongst all classes. I do not think the fact of a man's having once seen that kind of practice is sufficient proof of his sympathy with general practitioners. I should like to ask candidates—1. Are you now in *bonâ fide* general practice, with union and club appointments, and *do you intend to remain in your present position?* 2. Will you aim at raising the standard of general education to the level of that required in most foreign countries—say that of a B.A. degree at Oxford or Cambridge? I am, Sir, yours truly,

Woolwich, Oct. 4th, 1886. THEODORE MAXWELL, M.D.

To the Editor of THE LANCET.

SIR,—The circumstances that led to the formation of a committee whose object should be to endeavour, firstly, to find who would be likely to be the best representatives of the profession on the General Medical Council, and, secondly, to induce these to become candidates, are so obviously misunderstood that we venture to ask you for space for some words of explanation. Up to the date of the Brighton meeting there were, so far as was known, only seven gentlemen before the profession as candidates. Of these seven, five were heard to speak at that meeting in one capacity or another, so that many, if not most, of the members of that large assemblage had the opportunity of forming an opinion as to their fitness, in one important particular, for the honorable position to which they aspired. Two, Dr. Richardson and Dr. Glover, we believe, were not heard. Some at least of those who listened to the gentlemen in question, deemed that it was not inconsistent with the highest respect for them personally, to consider whether, from among the 17,000 practitioners of England and Wales, it might not be possible to induce a few to appeal to the suffrages of the profession who, if not better as men, should be better as representatives. No one else seemed inclined to come forward, and

Digitized by Google

the time for action was very short. The only possible way of arriving at a conclusion on what all will admit to be a most important matter was to consult gentlemen from various parts of the kingdom concerning it. This led to the summoning of the first small conference at Brighton. If the majority of those who attended it had considered that it was unlikely that any better representatives could be found, nothing further would have been done. But thinking otherwise, they resolved to take into their counsel as many as could be reached in the very short time possible to them. The number ultimately obtained was 360, from 163 different places, and nothing but want of time prevented this number from being increased ten ro twenty times. But to call these 360 gentlemen (thus without any pressure or influenec uniting themselves from such various quarters) "a small clique," is surely to employ language in a very unusual sense. The committee exercises no function beyond that of honestly to select gentlemen who in its judgment would be thoroughly able representatives; and it expects from the profession nothing more than that unbiased consideration which such an honest endeavour should secure for it. It accepting the verdict of these 360 gentlemen, we do not claim that they represent the whole profession, but, considering the number of districts represented and the decided character of the vote, it may be fairly taken as an indication of the feeling of a large body of the profession. To speak of the action of the Birmingham meeting as the action of a caucus is, again to use language in a sense which a moment's reflection must show to be incorrect. A caucus has made up its mind beforehand, and meets but to save appearances; but the thirty-five who met in Birmingham could have no possible means of knowing beforehand what were the opinions of the 360 living in all parts of the country on the names to be submitted to them, and they would not have made the experiment of a poll unless they had been honestly anxious to find this; out and the committee submits what it has done, its reasons for doing it, and its methods, with great confidence to the impartial judgment of the profession.—We are, Sir, yours faithfully,

WILLIAM CARTER,
Oct. 5th, 1886. HUGH R. KER.

To the Editor of THE LANCET.

SIR,—In your article in THE LANCET of October 2nd on the Direct Representation of the Profession on the General Medical Council you couple my name with that of Dr. Jacob, and say we are officials of a corporation whose representation plays already a larger part in the Council than probably any of its members. To associate Dr. Kidd or Dr. Jacob with Professor Macnamara would, you say, be a work of supererogation, and you urge the election of a genuine general practitioner to the Council instead of either of us.

Now, Sir, I beg to say that, so far as I am concerned, I am not an official of any corporation. For many years the Fellows of the College of Surgeons have done me the honour of electing me, year after year, a member of their Council. I have thereby acquired a large experience in the management of students, the control of their education, and the conduct of examinations, and I have been enabled to initiate and assist in working out improvements in the systems of education and examination which are now, I believe, universally admitted to be of a most valuable and important character. The chief and most important work of the General Medical Council is to supervise and improve medical education and examination, and thereby elevate the status of the profession and make it more useful to society, and it is because of the experience I have gained in this work through my connexion with the College of Surgeons that I have ventured to ask my professional brethren to elect me as their representative. It is, I am sure, unnecessary to remind you that the duties of the General Medical Council are strictly defined by the Act of 1858, and that they can take no cognisance whatever of anything ontside the four corners of the Act, whether it be the privileges of army medical officers, Poor-law or dispensary officers, general practitioners, or others, and that their highest duty is the supervision of medical education.

I am, Sir, yours faithfully,
Dublin, Oct. 6th, 1886. GEORGE H. KIDD.

*** We cannot say that Dr. Kidd's letter in any degree changes our opinion. Dublin physicians and surgeons have hitherto monopolised the Irish seats of the Council. No less than five do so at the present moment. For another to gain the sixth seat will be hard indeed on the practitioners of Ireland.—ED. L.

PHARYNGEAL AND LARYNGEAL "NYSTAGMUS."

To the Editor of THE LANCET.

SIR,—I am indebted to Dr. Gowers for permission to publish the following observations I have made on a patient under his care at University College Hospital. The patient, a girl aged twelve, has a cerebral tumour, and presents the symptoms of reeling gait (with a tendency to fall backwards and to one side, usually the right), vertigo, intense occipital headache, constipation, vomiting, ocular nystagmus, but no optic neuritis. The pulse is usually 100. These symptoms have been present for the last fifteen months. The ocular nystagmus is vertical and horizontal, occurs at the rate of 180 to the minute, is slightly increased in frequency during accommodation for very near, or in looking at far distant, objects. On examining the throat, I noticed the superior constrictor of the pharynx to be in a state of constant rhythmical movement in a horizontal direction, as if the posterior pharyngeal curtain were being rapidly drawn together, the twitchings occurring at the same rate as the movement of the eyes, 180 to the minute. The movement does not affect the soft palate or pillars of the fauces, the faintest possible tremor only being transmitted to them from the action of the adjacent constrictor. By pressing the point of a quill pen against the pharynx and pivoting the quill on a pin held fixed against the upper teeth, I have been able to write with the feather-end a tracing of the movement on sphygmograph paper. The laryngeal muscles are similarly affected. The arytenoid cartilages are seen rapidly gliding to and from each other synchronously with the movement of the pharynx. When the patient is breathing quietly the main movement of widening of the glottis during inspiration is interrupted by slight twitches, and similarly the movement of respiration. When the patient stops breathing the cords gradually close with five or six contractions, till they finally lie parallel and close to each other; here they remain, undergoing only a slight tremor till the patient recommences to breathe. I have had this patient under observation for over two months, and the movement has been always present. There is now a slight alteration in the state of the larynx, in that the left cord twitches more than the right, and the cords do not so nearly close when the patient stops breathing. I am not aware that a movement of this kind has been previously described, and I am anxious that it should be looked for in cases of intracranial tumour, so that its localising value may be determined. It is possible it may throw some light on the etiology of ocular nystagmus, and it may be of value to the surgeon, perhaps, in showing pressure on the medulla, and so assist in the diagnosis of the position of a cerebellar tumour. As regards the term "nystagmus" applied to the pharynx and larynx, its association and synchronism with the ocular nystagmus, and the fact that movement of the eyes in a horizontal direction is called "nodding," would seem to warrant a slight departure from strict etymological accuracy.

I am, Sir, yours truly,
HERBERT R. SPENCER, M.B., B.S. Lond.,
Oct. 1886. House Phys. Univ. Coll. Hosp.

TREATMENT BY MASSAGE.

To the Editor of THE LANCET.

SIR,—It will be a surprise and a shock to many of your readers to learn from THE LANCET of this week that the practice of massage is not to be acquired under two years, and some may even venture to ask whence the extreme elaboration of detail which this lengthened apprenticeship implies derives its sanction. It seems incredible that any manipulation of the body which human ingenuity can devise should be learnt so slowly. Divide the frame into as many departments as you will, exclude those parts which are inaccessible to massage and those which it would not venture to approach, and there remains but a limited area to which Dr. Weir Mitchell's method is applicable. Let the modes of rubbing, stroking, pinching, and kneading be multiplied to the utmost, and far beyond the reach of

Digitized by Google

language,—even then all possible contrivances will be exhausted before two years have run out. But if two years, why not ten? It may be confidently asserted that there is no digital use whatever needing two years for its acquirement that does not go on advancing towards perfection so long as the mind which informs the fingers retains its vigour. Massage takes rank with music and the Fine Arts.

To all this I venture to oppose the opinion that the manipulation of the body surface, which some call "massage," and which aims at supplying the place of voluntary muscular exercise, does not need two years to learn, nor two months, nor, with an apt scholar, two weeks. It is with massage as with other skilled exercise—as with fly-fishing and cricket and tennis. Some pick it up very readily, even from the mere observation of the skilled rubber. Some can never learn massage at all. Anyone not acquiring a fair skill after a month's training may begin to despair of ever acquiring it. It is a knack, and admits as many gradations of expertness as do the games just mentioned. But the fullest expertness is not a question of time but of natural adaptability. To suppose otherwise is to mistake both the object of massage and the nature of the faculty on the part of the teacher to which it makes appeal. These are no statements of mine, they are the substance of the teaching of many authorities, including Dr. Weir Mitchell, the original proposer of the treatment, and Dr. Playfair, who first introduced it into this country. One of the best operators at the Westminster Hospital Home for Nurses learnt it of Dr. Weir Mitchell "in a few lessons." He was so well satisfied of her expertnesss that he employed her on his own patients and wished her to remain in America. Her sister, whom I have just now seen, learnt of this other "in a week." Both of these sisters can quote a long list of successful cases, and their competence is attested by several well-known physicians, who have had proof of their skill. One of the earliest employers of massage in this country is the Lady Superintendent of the Home Hospital in Fitzroy-square. She has taught many; and patients needing the treatment are constantly under her supervision. The hospital has been visited by Dr. Weir Mitchell himself, who thoroughly approved of the system there in vogue. This lady believes that an apt learner can acquire massage in six lessons, while she repeats precisely what has been told me in other quarters, and especially by the matron of my own hospital (to whose kindness and interest in the matter I am much indebted) as to the wide difference between one nurse and another in picking up the trick of rubbing. From such practical testimony, let me turn to the voice of the profession. Next to Dr. Weir Mitchell, I suppose the authority of Dr. Playfair will be deemed the highest. He writes in terms which he allows me to quote, and which are sufficiently indicated by the following extracts:—"Massage is a very simple thing which has been made complex by the absurd way it has been written on abroad, and the divisions and names given to it." "Half-a-dozen lessons I consider quite enough if the learner has natural aptitude." The statement that two years are needed is manifestly absurd. "I am inclined to think that just now massage is very much overdone and often used in quite unsuitable cases." The fact is, I suspect, that massage, like other therapeutic agents that attract attention, like the hypophosphites and salicine and salicylates, is passing through its stages. First, the warm, and often indiscriminate, praise; next the statement, and doubtless the genuine belief, of some practitioners that in their own hands the new agent can be made to yield a virtue which others fail to extract from it; and, finally, the settling down of belief as to the real value of the treatment in question. And if it be so with drugs, how much more with a method of manipulation which confessedly needs skill, dexterity, and practice. Let us be content, then, to leave "massage" to make its own way like other remedies, in the full assurance that the settling day will come by and bye, when its precise value will be finally determined. And so, no doubt, in the main it will be; and in that persuasion I would gladly have spared myself a task of criticism which, in the circumstances, is exceedingly distasteful. But there are others to be considered, and it is but just that a word should be said on behalf of those to whom many of us are deeply indebted, and who may not speak for themselves. Massage is now largely resorted to: there is probably no hospital in London, and no nursing home of repute, which cannot furnish trained rubbers (as I still venture to call them) who are thoroughly competent, and whose ability is proved by the patients they have helped to cure. The time will soon come, it may be hoped, when the same may be said of every town in the kingdom. It is quite easy to disparage these quiet workers, who may be at least trusted to make no protest and no claim of their own. It is less easy to prove by results that the refinements which have been imported from the Continent add anything whatever to the virtue of Dr. Weir Mitchell's method. The treatment is still on its trial, but the facts in regard to it are in small compass and accessible to all. Massage may be so far popularised as to become a valuable help to practitioners in a class of cases heretofore singularly hopeless and pitiful, or it may ultimately fall into the hands of a few "professors," who will make of it a "speciality," or even a trade.

I am, Sir, yours obediently,

OCTAVIUS STURGES,

Oct. 4th, 1886. Senior Physician to Westminster Hospital.

"INFANT FEEDING."

To the Editor of THE LANCET.

SIR,—I regret I have not been able to reply to Dr. Marshall's letter earlier. I have received a great many communications in reference to my article on Infant Feeding, including one from the United States, showing the wide interest the subject excites in the profession.

Dr. Marshall says that "physiology and experience both negative" my plan. Surely this is putting the cart before the horse. Physiology, like other sciences, is constructed by drawing deductions from well-verified facts—it does not condemn asserted facts untested. If Dr. Marshall, and other men equally as well placed as he is, try the plan I advocate and find it fail, I will bow to their decision; but it is hard to be told that science is able to condemn it off-hand, seeing that a physiological writer has placed the average life of a physiological fact at three years! My article did not profess to treat fully the subject of milk-feeding pure and simple, so I did not give full details as to methods I have pursued in that direction. I am acquainted with "Frankland's Milk," but the process advised seems to me too complicated for universal use. Half milk and half water certainly gives a larger proportion of caseine than human milk (indeed, Dr. Meigs of Philadelphia, U.S., asserts, and to my mind proves, that the amount of caseine in human milk is certainly under 2 per cent.); but one part milk to two parts of water is, in my opinion, starvation in disguise; while adding cream and whey to water or to milk is not only a complicated process for poor ignorant people, but it involves keeping the milk for twelve hours before it is used. Considering that cow's milk has an acid reaction to begin with, while human milk is slightly alkaline, and considering how readily the milk of cows kept in sheds (and therefore fed on roots and grains) ferments, I do not think cow's milk twelve or probably fifteen hours old is likely to be as digestible as absolutely fresh milk. My own children were fed with milk from one cow; various proportions were tried of water, but all suffered severely from flatulent colic and curdy motions until the milk-and-water was thickened with a well-known food, which I believe contains bicarbonate of potash as well as malt and flour. After this the children improved in every way, and, I think, might now be shown as models of health. As regards the interval between the feedings, I have always recommended an hour and a half during the first week or two, to be gradually lengthened to two hours, whilst at some time during the night there ought to be an interval of at least four hours to give the digestive apparatus time to rest. I also always recommend that two or more bottles should be used, that at night a basin of water should be kept by the bedside, and that as soon as the child has sucked as much as it will, whatever is left is to be thrown away, and the bottle and tube placed separately in the basin of water. I still maintain that reducing the caseine "to digestible limits" is not the only problem in adapting cow's milk to infant digestions. I feel sure I am right in saying that, at all events, part of our problem is how to make the curd digestible. Mechanical effects do not seem to be sufficiently weighed, but they cannot be ignored. Take as an illustration the familiar laboratory experiment of making oxygen: black oxide of manganese helps the process, though not chemically. Again, I have read that certain savages of Patagonia of the lowest type, when severely pressed by

Digitized by Google

famine, mix earth with their scanty food to add to its bulk. The mechanical effect of the earth must be to allay the pangs of hunger, or they would surely never resort to such an eccentric mode of feeding.

In conclusion, I again assert, and beg of your readers to test, verify, or reject, as the case may be, my assertions, (1) that thickening one or two bottles a day of the milk and water used is quite a different thing from feeding on farinaceous food; (2) that milk-and-water so thickened is more digestible than milk-and-water alone; (3) that a diet of milk-and-water with a teaspoonful or so of farinaceous food per diem will cause a greater increase of weight, with healthy look and firm muscles, than an equal quantity of milk reduced to cream-water and whey or curdled with rennet.

I am, Sir, yours faithfully,

Southborough, Tunbridge Wells. E. PAGET THURSTAN, M.D.

A NEW CULTURE MEDIUM FOR MICRO-ORGANISMS CAPABLE OF WITHSTANDING HIGH PRESSURE.

To the Editor of THE LANCET.

SIR,—Having found agar-agar, in addition to the difficulty of obtaining it, somewhat inconstant as a culture medium, I have for some little time been experimenting in the laboratory of Professor Chiene with a jelly derived from Irish moss. The jelly so obtained is much less opaque than agar, and evidently more nutritious in itself, in that some micrococci and sarcinæ are able to grow in it without the addition of any peptone or meat juice. The method of preparation is of the simplest. Two ounces of the finest selected Irish moss are macerated over night in eighteen ounces of water in a beaker; then in the morning it is placed in the steam steriliser, and kept at the boiling point of water for the period of an hour and a half, being well stirred up occasionally. At the end of this time it is strained through a flannel, or (preferably) felt bag, two or three times, when it is found to be fairly bright. As a considerable quantity of refuse matter remains in the bag, the quantity of material derived from the moss and represented in the jelly must be considerably smaller than the actual weight of moss used. The jelly so obtained will be found on cooling merely to gelatinise, and yet one finds it to withstand a temperature of 31° C. before liquefying, but if it be evaporated to ten ounces, it is found to be capable of being exposed to a temperature between 50° and 55° C. before liquefying. In this state, if a test-tube be filled with it, it is found to present the appearance of water with only a slight degree of haziness. In order to render this more nutritious, and so better fitted for the requirements of the growth of the generality of micro-organisms, I add to it the materials recommended by Dr. Klein—namely, beef peptone and ordinary cane sugar. If we add to the jelly 2 per cent. of the former and 1 per cent. of the latter, the result is a jelly almost as bright as nutrient gelatine and infinitely more so than agar, while the simple method of preparation and the price (Irish moss is about one shilling per pound) have much to recommend it.

I remain, Sir, your obedient servant,

ALEX. EDINGTON, M.B., C.M.,
Assistant to Prof. of Surgery, Edin. Univ.

Edinburgh, Sept. 28th, 1886.

GRANULOMA FUNGOIDES.

To the Editor of THE LANCET.

SIR,—As you refer in your number of Oct. 2nd to a case of this extraordinary affection described by me at the Pathological Society in May last and reported in THE LANCET, and as the disease has lately attracted a great deal of attention on the Continent, perhaps you will allow me to say a word on the most recent aspects of the subject.

The hypotheses of Drs. Hochsinger and Schiff that the disease is due to the presence of micrococci in the tissues, and that of Professor Rindfleisch, which refers it to cocci in the bloodvessels, though each has been put forward with great confidence, cannot either of them be regarded as proved. In a paper to appear in the forthcoming Transactions of the Pathological Society I have given reasons for thinking that the "cocci" of Hochsinger are not micro-organisms, but protoplasmic granules occurring in certain cells, and that the organism which Schiff cultivated from the tissues was in all probability the almost ubiquitous Staphylococcus pyogenes aureus, with which it appears entirely to agree. Professor Rindfleisch's observations are, as I have pointed out, equally open to question. There can be no doubt about their objective accuracy; but the cocci he describes would appear to be rather connected with a septicæmic process, of which his patient died, than with the original chronic disease. On the whole, then, I have ventured to conclude either that the disease is not bacterial, or that the right organism has not yet been found. My own observations (confirmed by those of several pathologists in this country) gave a negative result; and so did cultivation experiments made in the laboratory at St. Thomas's Hospital by Mr. Ballance.

I am induced to trouble you with these lines, more especially because two new memoirs have appeared on the subject since my paper was sent in. One is that of Hochsinger and Schiff, to which you refer, in which they undoubtedly describe more extensive culture experiments, but do not bring any further proof that their cultivated organisms caused the disease. The other is a paper by Professor Koebner of Berlin (*Fortschritte der Medizin*, Sept. 1st), where the bacterial theory of this disease is combated by arguments which are almost identical with those used by me in the Pathological Transactions, and are founded on observations entirely agreeing with ours in this country as regards the absence of micro-organisms. These views were, I have just heard, brought forward at the late Medical Congress at Berlin, and were substantially confirmed by Neisser. The Berlin observations were evidently as independent of mine as mine of them, so that their coincidence is a valuable mutual confirmation. The same, I cannot but expect, will be the result of the investigation of other cases of the same disease, which may from time to time occur, unless, indeed, some day the not-impossible bacillus should be detected. In the meantime the moral is that of the immortal cookery-book—"First catch your hare."

I am, Sir, your obedient servant,

Wimpole-street, Oct. 4th, 1886. J. F. PAYNE.

THE TREATMENT OF CASES OF OPERATION FOR CATARACT.

To the Editor of THE LANCET.

SIR,—Mr. Snell's paper on the treatment of cataract, published in your issue of the 18th inst., leads me to suppose that the following method of dressing, which I have used in nearly all my cataract operations and iridectomies for several years, may be new to some of your readers. Strips of salicylated isinglass plaster are cut two inches and a half long and rather more than an eighth of an inch wide. As soon as the operation is completed and the lids closed, a strip is damped by drawing it over a pad of Gamgee tissue dipped in warm water, and is then applied along the margin of the upper eyelid so as to reach from the bridge of the nose to beyond the outer canthus; another is applied parallel to the first along the edge of the lower lid, and a third at right angles to the other two, reaching from above the eyebrow to the cheek. Care must be taken to make this strip stick firmly to the other two, and this is easily managed if it is damped to the proper degree. The eye not operated on is secured in the same manner, or sometimes the strip on the lower lid is omitted. In a few minutes the plasters are dry, and no further dressing of any kind is needed. By this means the eyelids are kept immovable without any pressure; any swelling which may occur is at once visible; the discharge has free exit between the edges of the lids, and can be removed by a sponge or pad of wet cotton-wool without disturbing the dressings. The salicylic acid in the plaster acts to some extent as an antiseptic. I have never had any trouble from the plasters loosening by the discharge and allowing the eye to open. Occasionally the ends of the plasters curl up a little, but this is easily remedied by damping them down again. Usually about the fourth day the plaster is softened by laying a pad of wet Gamgee tissue over the eye for a few minutes, and then removed and a similar dressing applied. I know of no drawback to the method, and confidently recommend a trial of it by your readers.

I am, Sir, yours obediently,

York, Sept. 27th, 1886. TEMPEST ANDERSON, M.D.

THE FIRST PROFESSIONAL EXAMINATION IN SCOTLAND.

To the Editor of THE LANCET.

SIR,—Will you permit me very briefly to reply to "M.D. Glasgow," who writes in your issue of the 2nd inst. regarding the first professional examination in Scotland? Your correspondent speaks of the student being confronted with chemistry, botany, and natural history (i.e., zoology) after passing his preliminary trial. He alludes to the "width" of these sciences, and, by implication, would have us believe that the medical student is forced to become little short of a specialist in each. I cannot speak either for Edinburgh or for Aberdeen, but as I have held the position of examiner in botany and zoology in the University of Glasgow for ten years past, I may be credited with a very fair knowledge of the amount of biological information the Glasgow student is required to possess for success in passing his first professional examination. Chemistry I leave out of consideration, for although "M.D. Glasgow" apparently includes this subject in his sweeping assertions, I do not think any sane person would dream of maintaining that a medical student should be otherwise than a fairly competent chemist. As regards botany and zoology I assert, without fear of any contradiction worthy the name, that at Glasgow University any student who shows a fair, and by no means necessarily minute, acquaintance with the broad facts of these sciences is certain to satisfy the examining board. We do not look for the *minutiæ* of biology from medical students, but we do expect them to possess what hundreds of students yearly do contrive to acquire—namely, a broad acquaintance with the fields of animal and plant life. I am at a loss to understand the mental calibre of the students your correspondent speaks of as having again and again been "plucked" in their first professional examination, save, indeed, on the theory that there are certainly a proportion of students who will not take the trouble to acquire even the reasonably limited knowledge needed to pass. My experience as an examiner—and I will add as a teacher of biology also—is that a certain class of students never will pass the first professional or any other examination whatever. These are the unhappy few who think themselves hardly used, because when, for example, they have informed examiners that a fern is a dicotyledon, or that a crab is a vertebrate animal, the said examiners refuse to credit them with the knowledge necessary to pass even the simplest of trials. Add to this that the intellectual demands made upon medical men nowadays are of very heavy character, and that the doctor is expected to be at least as intelligent a man as the schoolmaster or the clergyman; and I fancy "M.D. Glasgow" must admit that a knowledge of biology—possessing as it does intimate bearings on the nature and cure of disease—is by no means the least valuable of the mental furnishings of the modern physician. I am, Sir, yours obediently,

Edinburgh Medical School, Oct. 2nd, 1886. ANDREW WILSON.

THE MEETING OF GERMAN NATURALISTS AND MEDICAL MEN IN BERLIN.

(From a Correspondent.)

THE fifty-ninth meeting of the Society of German Naturalists and Physicians (corresponding to the combined British Association and British Medical Association), which has just taken place in Berlin, has been one of the most brilliant gatherings of the kind, both as regards the attendance and the scientific outcome. The scientific work at these meetings consists in the delivery of lectures of general interest before the whole assembly on days set apart for the purpose, in the reading of papers, and in demonstrations in the different sections.

As specialism exists in Germany to a greater degree than in England, the number of sections at these gatherings is very large, and this year there were thirty sections, of which twenty-one were more or less medical. In spite of the subdivision of the work (thus I noticed a section on pharmacology, one on pharmacy, one on general hygiene, one on military sanitary science, and one on medical geography, climatology, and hygiene in the tropics), all the sections were well attended, and some had as many as 400 members. The different hospitals, scientific institutes, and museums were also thrown open for inspection, and in some special demonstrations were given. There was also held in connexion with the Congress an exhibition of drugs and scientific instruments used in the different branches of medicine and the natural sciences.

Deferring for the present an account of the work done in the sections, and of the exhibition of instruments, I wish, to-day, briefly to notice some of the general addresses. At the first open meeting Professor Virchow gave the introductory address, in which he briefly sketched the origin of the Association, its aims and objects, and its immense development, and alluded to the scientific activity of the German race as a guarantee for the growth of the German nation. "In the severe struggle for existence only those nations will survive which succeed in unravelling the mysteries of nature in new directions, and in placing at the service of man the forces which we find spread out in the world in a profuse manner." He then alluded to the connexion of the natural sciences with medicine, which connexion was still kept up by the German Association, in contradistinction to its English sister Association, and dwelt at length on the new method, the mechanical method, of research (in the sense in which Leibnitz uses the words, "Omnia in corporibus mechaniæ explicari posse"), which, by replacing the so-called natural philosophy (*Naturphilosophie*) and speculative philosophy, remodelled the whole of biology, and gave the basis to all scientific inquiries. Darwin, in his famous work on the Origin of Species, tried to solve the question of descent, not in the sense of the old natural philosophy; he did not discuss general probabilities, but looked for the several practical cases; he did not search for special organic powers, but tried to find the mechanical effect of natural causes. The same method has been pursued ever since; and if in recent years rapid advances have been made, especially in the study of infectious diseases, the aim and the method have remained the same—the scope only of our investigations has been altered. "Our modern transactions are characterised by the spirit of empirical but methodical investigation, the spirit of practical synthesis, the spirit of brotherly co-operation in the several branches of the wide scientific field."

Dr. W. Siemens gave an able address on our Scientific Age, and was followed by Professor Bardeleben of Jena with a paper on "Hand and Foot," in which he compared the hand with the foot on the basis of comparative-anatomical and palæontological data. He then discussed the origin of the vertebrate limbs, and contrasted Gegenbaur's theory with the more recent one of Thacher, further developed by Mivart and the lamented Balfour, concluding with a number of aphorisms more suitable for the lay portion of the audience—such, for instance, as the adaptation of the terms "foot" and "hand" to such various purposes as standards of measurement, as the basis of our numerial system, and so on.

At the second general meeting Professor Cohn (Breslau) read a most fascinating paper on "Questions of Life" (*Lebensfragen*), which showed that the great problem is not yet solved, and that in the living organism there are forces which, though they must be mechanical, as they put bodies in motion, yet cannot be split up into components of atomic molecular forces. "The gulf which separates life from death, organic from inorganic bodies, is not closed, and none of our hypotheses will help us to bridge this gulf." He was followed by Dr. Schweinfurth with a paper on a geographical subject, and by Professor His on the "Development of the Zoological Station at Naples and the growing necessity for Scientific Central Stations." The lecturer dwelt on the advantages such institutions, if properly worked, would have for the study of many questions of physiology and embryology. In these institutions collective investigation on some subjects—as, for instance, the finer structure of the brain—could be carried out—work which could not be done by a single individual. They should form a sort of library or museum, accessible to all scientific inquirers.

Professor Stricker (Vienna) then gave a demonstration with his powerful electric microscope, and showed how useful the instrument is for lecture purposes.

At the third and last general meeting there were three addresses, only one of which, that of Professor Bergmann of Berlin, was of medical interest. Professor Bergmann spoke

Digitized by Google

of the relations of modern surgery to internal medicine, the triumph of surgery due to the antiseptic method of Lister, and the scientific development of surgery. Wounds can now be made to heal so readily that surgery has invaded the territory of medicine, and serious operations on internal organs are performed, and often, also, operations merely for the purposes of diagnosis. Internal medicine, occupying itself largely with those disease-germs which are brought to the organism from without, tries to wage war against these germs in their native elements—the air, water, and soil,—and is becoming more and more preventive.

I propose in a future communication to allude to the work done in some of the sections, and to some other matters in connexion with the Congress.

LIVERPOOL.

(From our own Correspondent.)

OPENING OF THE LIVERPOOL UNIVERSITY COLLEGE.

The formal opening of the Winter Session of the University College, Liverpool, was held at St. George's Hall, on Saturday last, under the presidency of Lord Derby. In opening the proceedings, the noble chairman said he believed it was no exaggeration to say that "the record for the year just ended is satisfactory in nearly every respect. No previous session has shown so marked an increase either in the number of students or the amount of fees. The chief event of the year is the completion and opening of the new chemical laboratory, which was inaugurated by an address from Sir Lyon Playfair in March last. The Council since that date have had six months' experience of the working of the arrangements then completed, and no serious defect or oversight had been discovered, those who are best qualified to judge considering the laboratories as equal for completeness and efficiency to any now existing in the British islands. Another matter has engaged a good deal of public attention. Two years ago, acting on a strongly expressed public feeling, the Senate devised a two years' course of study suitable to young men who were training themselves for a business life. The scheme was discussed over and over again; many of the leading firms in Liverpool were consulted; it was adopted by the governors in the autumn of last year, and no pains have been spared to obtain for it the approval and support of the principal trade associations of the city, which support has been given in a simple and very practical form. Most of the leading banks and insurance companies and above 350 private firms have agreed to recognise the certificates granted by the College to those who pass creditably through the proposed course—not, of course, as an absolute claim to employment, but as a recommendation to which they attach importance; and in many cases they will lessen by one year the ordinary term of apprenticeship in favour of candidates who may be so qualified—which is a kind of help doubly valuable, both because it furnishes a practical inducement to young men to go through this course, and because it shows an amount of sympathy among business men with the work which the College is doing, which strengthens our hands in appealing to the public for further help. Mr. G. Holt, already a large donor, has very liberally presented to the College the sum of £2000 for the advancement of medical study, and that sum has been applied to the creation of two scholarships to be annually awarded to senior students of the medical school. And an entirely novel experiment has been tried in the establishment of ten very small scholarships for working men, yielding only £5 each, but involving, on the other hand, the necessity of attendance at two courses only of evening lectures. The object of them is to assist men not otherwise able to provide the cost of attending lectures and of the necessary materials for study. The Council is asked to do this, that, and the other, which is useful and desirable, and tries to meet the wants and wishes of the public; but does so, for the most part, at a heavy increase of expense. It is a good sign—a healthy sign—that the child should be outgrowing its clothes, but the parents must not complain if they have to pay for new ones. The College has grown very fast, and no men hereafter will ever venture to say again, what was said by many people a few years ago, that such an institution is not wanted or appreciated in Liverpool. 'Well begun is half done'; and the severest critics cannot deny that the beginning has been a good one." An introductory address was then delivered by Mr. Wm. Martin Conway, the Professor of Art, who selected as his subject "The Succession of Ideals." Lord Derby afterwards distributed the prizes to the successful candidates, and after votes of thanks had been proposed and carried to the lecturer and Lord Derby, both of whom briefly returned thanks, the proceedings terminated. The annual dinner was held the same evening in the Adelphi Hotel, under the presidency of Dr. Caton, at which a large number of medical practitioners were present.

"VIEWING" REMAINS.

Referring to the remarks in THE LANCET of last week under this heading, there is another phase of the subject which ought not to be ignored. A most experienced coroner's officer in this city, now retired, gave, among other experiences, this: that many a man dates the commencement of a career of intemperance to his first serving as a coroner's juror, and the effects upon him of "viewing" the body. In hot weather especially, the state of a body within twenty-four hours after death may be such as to try severely even those who are accustomed to such sights and odours—a condition which is intensified by the fact that the "viewing" cannot, as a rule, be until two or even three days after death, and frequently even longer than this. In Shanghai the coroner's jury comprises three persons; a county court jury in this country, five. If the coroner's jury is a desirable institution to perpetuate, might it not be reduced? And seeing what an utter farce the "viewing" is, it is high time it was dispensed with.

PREVENTION OF CRUELTY TO CHILDREN.

A summary of the work done during the month of September by the Society for the Prevention of Cruelty to Children amply justifies its formation. In that interval of thirty days the Society took up 58 new and 10 old cases, the former involving the welfare of 107 and the latter that of 12 children. Among the complaints were 2 of assault, 1 of excessive beating, 41 of general neglect, 2 of starvation; exposure, 21; sleeping out at night, 6; the remainder being cases of begging and of selling at night. In four cases the complaints were dismissed. Two children were committed to industrial schools, 36 were under the supervision of the School Board, 3 were placed in workhouse schools, 2 in hospitals, 3 with relations, and 22 with parents under visitation; 29 parents were cautioned; the remainder of the cases were disposed of in various ways.

HARVEST FESTIVAL AT THE ROYAL INFIRMARY CHAPEL.

On Sunday last the usual harvest festival was held in the chapel of the Royal Infirmary. The decorations, which were by the lady superintendents and their assistants, were very beautiful. The musical portion of the services was most ably rendered by the large staff of nurses and probationers, who, under the indefatigable organist, spare no effort in making the services every Sunday as cheerful as the surroundings of a hospital chapel will allow. The chapel was filled to overflowing, and Archdeacon Bardsley preached on behalf of the Samaritan Fund of the infirmary. This fund enables the chaplain (the Rev. W. Smith) not only to give some little help to poor patients, but also in many instances to alleviate the distress at a patient's house while the bread-winner is the inmate of a hospital ward. The offerings at the two services amounted to £7 9*s.* 1*d.*

UNIVERSITY COLLEGE, LIVERPOOL: MEDICAL FACULTY.

List of Scholarships, Exhibitions, Prizes, &c., 1885 to 1886: Scholarships and Prizes: Holt Tutorial Scholarships, A. W. Collins and J. E. Gemmel. Lyon Jones Scholarships, H. A. Burrowes, S. R. Knight (resigned), and A. J. Chalmers. Derby Exhibition: W. T. Thomas. Winter Session.—Third and fourth year subjects: Medicine: W. T. Thomas, silver medal. Surgery: W. T. Thomas, silver medal. Pathology: J. H. Abram, silver medal. Obstetrics: F. Kerans, silver medal. Second-year subjects: Advanced Anatomy and Physiology: E. Hale, Torr gold medal; J. Gould, bronze medal. First-year subjects: Elementary Anatomy and Physiology and Chemistry: R. H. Carlisle, Bligh gold medal; J. S. Sewill, bronze medal. Summer Session.—Materia Medica: J. Cunningham, silver medal. Botany: A. J. Chalmers, silver medal. Medical Jurisprudence and Toxicology: F. Kerans, silver medal. Practical Chemistry: A. C. Wilson, silver medal. Histology Prizes: First, Mr.

Digitized by Google

Hale; second, Mr. Grimsdale. Students' Debating Society Prizes: First prize for essay, Mr. Sanderson; second, Mr. Livsey. First prize for debating, Mr. Capper; second, Mr. Fox-Parry. First prize for specimens, Mr. Garth; second, Mr. Buchanan. Prize for medical cases, Mr. Abram; for surgical cases, Mr. C. W. Graham; for venereal cases, Mr. Leigh.

MANCHESTER.

(From our own Correspondent.)

OWENS COLLEGE.

WORK is being resumed for the winter session in most of the departments during the present week. In the arts, science, and law departments the Professor of Mathematics delivers an "introductory," and in the evening classes department an introductory address will also be delivered on Monday next; but, in accordance with the now established custom, the medicals will have no such opportunity of giving vent to the exuberance of their animal spirits, but, in lieu thereof, a conversazione was held last night in the College, which was very largely attended, between 400 and 500 visitors being present. The whole of the buildings were thrown open, and various scientific apparatus, &c., were shown for the instruction and amusement of the guests. The Dean of the medical school (Professor Young) gave his report of the work of the past year, and afterwards delivered an address on the future prospects of the College and University. Later on, Dr. Dreschfeld discoursed to a large audience on Pasteur and his inoculation method for the prevention of hydrophobia. On Thursday evening the annual medical dinner of the College will take place at the Queen's Hotel, under the presidency of Sir William Roberts.

HOSPITAL EXTENSION.

With a view to assist in raising the funds required for the proposed extension or rebuilding of St. Mary's Hospital, which has for some time past been in contemplation, steps have been taken for holding a bazaar next month in the Gentlemen's Concert Hall. The additions to the Hospital for Consumption by the erection of a new and more suitable building for the out-patient department are rapidly approaching completion; it forms a very compact and well-adapted building for the purposes required, and will be a great improvement on the make-shift accommodation hitherto provided in John-street. Twelve months ago, the committee of the Northern Counties Hospital for Incurables appealed to the public for the means to extend their hospital at Mauldeth Hall, as it had become quite full and many applications for admission had to be refused. As the result of this, a most handsome gift was received from a lady, Miss Kay, in the shape of a large house and grounds near Bury. These, having been taken over and adapted by the committee, were recently formally opened by the Bishop of Manchester. The accommodation here will ultimately provide for some forty additional patients, and will, for the present at least, render the extension of the original building unnecessary.

MILK ADULTERATION.

Our municipal authorities are still very vigorous in the prosecution of offending milk-sellers. Scarcely a week passes but we hear of cases in the police-court; and letters have not been wanting in the columns of the daily press, complaining that the milkmen are in some cases scarcely treated with fairness, and a vigorous defence was made in a recent case by counsel, to show that a milk containing only 8·3 of non-fatty solids was not necessarily a sophisticated one; but the magistrates were not to be moved, and convicted the offenders of wilfully tampering with the quality of the milk.

SANITARY PROGRESS.

The large tract of land at Carrington Moss, which came into the possession of the Corporation for the purpose of being utilised as a means for disposal of the refuse and night soil of the southern part of the city, is being rapidly prepared for this purpose, and commendable activity has been shown by the health department in the progress of this work. Another useful step recently taken by the Parks Committee of the Corporation is the acquisition of a portion of the brick fields at Rusholme, for a public recreation ground. The Open Spaces Committee, so ably presided over by Mr. Herbert Philips, has had much to do with this desirable object being brought about.

Our medical societies have commenced their work again, and at a meeting of the Owens College Medical Society, it was resolved to discontinue the use of the central room, &c., which was last year provided in the centre of the city, in deference to the views of some of the members that the college rooms were too far away from the centre of the town. The experiment has, however, shown that members prefer to go to the library and reading-room at headquarters—the central room having scarcely been used at all.

Manchester, Oct. 6th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

BERWICK.

THE bazaar in aid of the Bethnal-green Free Hospital was opened in this ancient border town on Wednesday last by H.R.H. the Duchess of Teck. The ceremony was regarded in the light of "an event" at Berwick, and was well attended. The bazaar was kept open two days, closing on Thursday night, and the result was a gain of over £500 for the charity.

INFANTILE DIARRHŒA.

Dr. Renton, medical officer of health at Chester-le-street, Durham, in his report to the sanitary authority for the past month, thus refers to the prevalence of infantile diarrhœa in the district:—"I find that diarrhœa, always our anticipated scourge at this period of the year, has been the cause of fourteen deaths; the whole of these fourteen deaths have occurred in infancy or early childhood, and I have no doubt that improper feeding has been the initial factor in each instance. It is noticed that amongst the greater number of the working classes very crude notions exist as to the proper nursing of those of tender years, and, what is still more to be deplored, they will not be taught, or they turn a deaf ear to the warning of the doctor. Thus, either from ignorance or wanton carelessness, the death-roll is generally swelled in the autumn months."

THE NEW HOSPITAL FOR JARROW.

The foundation-stone of the new hospital at Jarrow was laid last week. The site was well chosen, with good drainage, and is at a considerable distance from any dwelling—a matter of importance in a hospital intended as this is for infectious diseases. A brick wall is to be built round the site 9 ft. high, with pillars about 14 ft. apart. The administrative department will be two storeys high. On the ground floor will be the doctor's and matron's rooms, the kitchen, and dispensary, with scullery and pantry in the rear; while on the first floor will be bedrooms and baths. The ward block is to be 118 ft. long, and will consist of four wards, two nurses' rooms, and two bath-rooms. There will be two wards for females, entered from the south side of the building, and with accommodation for seven beds. The men's wards will be entered from the north side, and will have accommodation for six beds, with nurse's room, bath-room, &c. The sanitary and disinfectant block will be situated at the east part of the site, and will be fitted with washing appliances for thirty-nine patients. The building will be of brick with stone facings, and is estimated to cost £3107. This does not include the cost of the site, which was £500.

DR. J. G. HOUSEMAN OF NEWCASTLE.

Dr. J. G. Houseman has resigned his appointments at the Children's Hospital, the Eye Infirmary, the Throat and Ear Hospital, &c. He has determined to travel for a lengthened period—proceeding, I believe, in the first instance to China. Dr. Houseman has many friends in Newcastle and the north of England, and he will carry with him in his travels their best wishes for his health and welfare.

DEATH FROM LEAD POISONING.

An inquest was held here this week on another of these unfortunate cases, sadly too frequent amongst female white-lead workers. She was a married woman, aged thirty-four, and up to the time of her commencing employment at the

Digitized by Google

lead works had good health. In a very short time, however, she became subject to the poisonous influence of the lead, had convulsions and colic, followed by the usual train of symptoms, ending in death. The coroner, in summing up, said it would be a great advantage to the people employed at lead works if something could be invented to render their labour less dangerous. He was afraid, however, that the precautions which had been already brought into use were not resorted to as much as they ought to be by those who had to work in lead factories.

Newcastle-on-Tyne, Oct. 4th.

IRELAND.

(From our own Correspondent.)

QUEEN'S COLLEGE, CORK: THE MEDICAL SCHOOL.

The President, in his report just issued for the past session refers to his previous report, in which he dwelt upon the advisability of enlarging the scope of the teaching in the medical school, so as to enable it to perform efficiently the increased work imposed upon it, in consequence of the rapid growth of medical science, and the gradual enlargement of the medical curriculum of the Royal University. For this purpose he suggested the teaching of physiology, separated from that of anatomy, and the establishment of a special chair of physiology. He also recommended the establishment of two new chairs, one of human and comparative pathology, and the other of public health, including medical jurisprudence. The proposed enlargement of the scope of teaching in the Medical Faculty suggests the necessity of likewise improving the clinical teaching in the Cork hospitals, as any efforts to bring the teaching at the College up to the present level of medical science must remain almost fruitless without the thorough co-operation of the hospitals. The materials for practical teaching in the general and special hospitals, if the Union Hospital is included, which is now open to students, are very good, and the president suggests that the staffs of all the hospitals in Cork should unite for teaching purposes, classify the students who attend the Cork School of Medicine, and so arrange their clinical teaching that everyone might be able to get the full benefit of it. Under such an organisation the time of both teacher and student would be much economised; while better provision than now exists could be made for teaching junior students. At present these form part of the helpless crowd of young men, who, with a nucleus of real working students, follow the physician or surgeon from ward to ward, and who, lacking systematic preliminary knowledge of disease, are unable to benefit by the clinical teaching suited for the advanced students. Again, the staff of the larger hospitals should be increased by a number of assistant physicians and surgeons, who should conduct, under the direction of the senior members of the staff, a large part of the clinical teaching. In this way there would be formed a body of competent candidates accustomed to teach, and likely to keep themselves in the current of medical science, from whom to select persons to fill such vacancies as would from time to time occur in the staff. Clinical clerkships and dresserships also should be established, these important offices being given after a practical examination by examiners appointed by the associated hospital staffs, and a certificate given to each student at the end of his term of office.

ROYAL UNIVERSITY OF IRELAND.

Earl Dufferin has been selected to succeed the late Duke of Abercorn as Chancellor of this University. The election for a member of the Senate will take place towards the end of this month, when a very exciting contest may be expected.

NATIONAL ORTHOPÆDIC AND CHILDREN'S HOSPITAL, DUBLIN.

The committee of this hospital, having determined to move into larger and more commodious premises, have decided to issue an appeal for the necessary funds to enable them to secure a larger building and furnish the same up to all the modern requirements of a children's hospital. The institution is a deserving one, and it is sincerely to be hoped that the amount required may speedily be subscribed.

Dublin, Oct. 6th.

PARIS.

(From our own Correspondent.)

M. POLAILLON'S GASTROSTOMY CASE.

AT the meeting of the Academy of Medicine last week, M. Polaillon exhibited the patient on whom he had performed the operation of gastrostomy for the removal of a fork from the stomach, and to which you referred in an annotation in THE LANCET of September 25th. The operation has been most successful in all respects. The patient has remained quite well and hearty, and when presented he held in his hand the fork that he had swallowed. There was no symptom whatever of peritonitis, but immediately after the operation he was seized with jaundice, which lasted a few days. This was followed by a small abscess, which opened at the inferior part of the wound, but soon healed. No other untoward symptom occurred, and at the end of three weeks after the operation the man was able to get up and go about the garden of the hospital. There is evidently no adhesion between the incision of the stomach and that of the abdominal parietes, as that organ can be felt moving freely in the peritoneal cavity. The "suture perdue" was therefore a complete success, and reflects great credit on M. Polaillon, who performed the operation, and who was the first to employ this form of suture in such cases.

CYSTICERCI IN MUTTON.

M. Johannés Chatin, the newly-elected member and son of Professor Chatin, then ascended the tribune, and read a paper on "Ladrerie" in sheep. Up till now the flesh of sheep was considered, when eaten in a raw state, to be as dangerous as pork and beef, owing to the presence of cysticerci in the muscular tissue. According to M. Chatin, however, there is nothing to be apprehended in eating mutton raw, as, although the presence of cysticerci has been established in the flesh of sheep, they are never found in such numbers as to determine a veritable "ladrerie," and, as they do not attain the development of the cysticerci of pigs and oxen, there is no danger of their transmission to the human species. M. Chatin therefore concludes that mutton in its raw state may be safely prescribed whenever such a form of treatment is indicated.

ABNORMAL PNEUMONIA.

Dr. Netter of Nancy related a case at the Congress recently held at that town of an individual with a palustral diathesis, who was suddenly seized with pneumonia, most probably of the same origin, for instead of following its ordinary course the malady presented a certain intermittence. Sulphate of quinine was prescribed by way of trial, and a few days afterwards the patient was cured. The author thinks that in cases of abnormal pneumonia it would be useful to examine the patient, not only morning and evening, but several times during the day, as any slight remission might pass away unperceived. If Dr. Netter had not examined his patient during the febrile remission, he would not have recognised the particular nature of the affection.

Paris, Oct. 5th.

THE SERVICES.

ADMIRALTY. — The following appointments have been made:—Staff Surgeon James Dunlop, to the *Egeria;* Surgeon Alexander F. Harper, to the *Algerine;* Surgeon Howard J. C. Todd, to the *Ganges;* Surgeon A. S. Nance, to the *Swallow;* and Deputy Inspector-General Francis W. Davies, to Jamaica Hospital.

RIFLE VOLUNTEERS.—1st Wiltshire: The following Surgeons are granted the honorary rank of Surgeon-Major:—G.C. Taylor, M.B., and F. F. Lee.

SCARLET FEVER EPIDEMIC IN DUNDEE.—No less than 263 fresh cases of scarlet fever were reported to the sanitary authorities of Dundee during the month of September. They have occurred principally in the more crowded parts of the town, although no district has been entirely free of the epidemic.

Obituary.

ENRICO MARZARI.

PADUA has suffered severely in these days, not only from cholera and small-pox, but from the loss of distinguished practitioners who have worn their lives out in combating the two epidemics. As if the death of the eminent surgeon and clinical teacher, Professor Francesco Marzolo, were not sufficient, she has now to mourn that of his favourite pupil, Dr. Enrico Marzari. After a highly creditable curriculum at the University of Padua, Marzari became Professor Marzolo's assistant, and under the rigidly scientific and largely benevolent auspices of that able consultant he made himself known and esteemed by the profession and the public. He then took his degree of "In Medicina Doctor," with special honours for practical as well as theoretical proficiency, and at once embarked on his professional career. He was making rapid progress, accelerated by the premature decease of his patron and teacher Marzolo, to whose *clientèle* he succeeded, when symptoms of cardiac mischief, hereditary in his family, began to show themselves. He struggled on, however, and for two years continued in his daily widening path, in spite of warnings that would have been final with a less intrepid nature. The epidemic of small-pox gave him much to do among the less-favoured classes, who never appealed to his benevolence in vain, and he was barely recovering from the effects of over-exertion thus induced when the cholera epidemic assumed alarming proportions. Again Marzari was at the front, but this time with sadly diminished strength. Spasmodic pain of an aggravated kind was rapidly making life a burden to him, when on the 30th ult. he almost suddenly expired. A Paduan correspondent writes: "He falls a victim to zeal and duty. The sad announcement was received as something personal, not only by a wide circle of friends and admirers, but by a still wider circle of the poor, to whom he was for years an unwearied benefactor. To his family he bequeathes no other wealth than that of a name honoured and cherished by all his fellow-citizens. His funeral was a touching spectacle; every rank and calling was represented at his grave; and the populations of San Leonardo and Savonarola, on whom most of his gratuitous attendance was lavished, closed their shops and draped their houses in black, as a token of their sense of loss."

JOHN PEARSON BELL, M.D.

DR. J. PEARSON BELL, whose death occurred on the 26th ult. at his residence in Hull, received his professional education at St. Thomas's Hospital and the University of Glasgow. In 1830 he became a licentiate of the Society of Apothecaries of London; in 1845 he obtained the degree of M.D. and C.M. at Glasgow University, and in 1860 the licence of the Royal College of Physicians of Edinburgh. At the time of his death the deceased was in his seventy-eighth year, and had for many years been connected with most of the public institutions, and taken part in the principal public movement in Hull. In 1875 he was appointed a magistrate of the borough, and for over fifty years he had a long and prominent career as a Freemason. In April last Dr. Bell's golden wedding was celebrated, when the Masonic brotherhood throughout the province showed their appreciation of his services by presenting to Mrs. Bell a marble bust of her husband. Dr. Bell was highly esteemed in Hull, and his death is much regretted by the inhabitants of that town.

THE PUBLIC HEALTH ACT IN SCOTLAND.—On the 21st ult. a man was fined five shillings at Greenock for removing by railway his daughter who was suffering from scarlet fever.—At Dundee, on the 23rd ult., a lodging-house keeper was fined half-a-guinea for neglecting to ascertain whether one of his lodgers was suffering from infectious disease.—On the 21st ult., at the same police-court, a woman who was charged with a similar offence was dismissed with a caution.

Medical News.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on Thursday, the 30th ult.:—

Barrett, Ernest, Elm-road, Dulwich.
Horner, Charles Julian, M.R.C.S., Fern-hill, Walthamstow.
Sibley, Walter Knowsley, Harley-street.
Stevenson, George, Edgware-road.

THE new building in connexion with the out-patient department at Westminster Hospital was opened on the 5th inst.

ON the 28th ult., a deputation from the Royal Commission for the Blind, Deaf and Dumb, Imbecile, &c., visited the Royal Albert Asylum.

DAVOS PLATZ.—This popular health-resort is to have the advantage of railway communication from Landquart. The line will be twenty-five miles in length, and will traverse Prättigau.

ENTERIC FEVER AT SWANSEA.—Enteric fever is again prevalent at Swansea, the outbreak being attributed to the access of farm refuse to a stream which runs into a reservoir which supplies the west end of the town.

MISS FLORENCE NIGHTINGALE has been compelled through illness to decline to unveil the statue of Sister Dora at Walsall on the 11th inst.; Mr. Gladstone also has expressed his regret at being unable to attend the ceremony.

AN inquest was held at Bangor in the north of Ireland on the 28th ult., on the bodies of two women whose death had been produced by irritant poisoning, caused by their having partaken of putrescent german sausage.

SCARLET FEVER IN OLDHAM.—At a special meeting of the Sanitary Committee of the borough of Oldham on the 4th inst., the medical officer reported that there had been within the last few days a large increase in the number of patients in Westhulme Infirmary. The cases are nearly all scarlet fever.

AT the meeting of the Liverpool City Council on the 6th inst., the medical officer of health recommended that, in consequence of the prevalence of scarlet fever in the city, additional hospital accommodation should be provided. After a lenghthened debate, the matter was referred to the Special Hospitals Committee.

SHEFFIELD MEDICAL SCHOOL.—The Mayor of Sheffield has announced his intention of calling a public meeting to promote the erection of a new School of Medicine in the town, the premises now occupied, and which were built in 1828, not being equal to the present requirements of the institution. A handsome sum of money has already been subscribed, but £2000 more is required. The Archbishop of York has consented to take part in the meeting, and Sir Andrew Clark has promised to visit Sheffield to speak at the gathering.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The following office-bearers have been elected for the ensuing session:—President: Dr. Alderson. Vice-Presidents: Mr. E. C. Barnes, Dr. Campbell Pope, Mr. Hemming, and Mr. Keetley. Council: Mr. Swinford Edwards, Dr. Hart Vinen, Mr. R. F. Benham, Dr. Owles, Dr. Thudichum, Dr. Bullock, Dr. Wells, Dr. Pickett, Mr. Gunton Alderton, Mr. Lloyd, Dr. Spicer, and Dr. Savill. Treasurer: Mr. F. Lawrance. Secretaries: Mr. H. Percy Dunn and Dr. Clippingdale. Auditors: Dr. Blenkinsop and Dr. Gloster.

WARNEFORD HOSPITAL.—At a special meeting of the governors of this institution held at Leamington on the 6th inst., it was proposed that, as at the Queen's Hospital, Birmingham, every out-patient should be required to pay a registration fee of one shilling. The honorary medical staff objected strenuously to the proposal, and it was urged that when all the attendant expenses had been defrayed the hospital would not benefit pecuniarily to the extent of £30. The plan was eventually rejected by an overwhelming majority, only three voting for it.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ANDERSON, JAMES, M.D., M.R.C.P., has been appointed Assistant Physician to the London Hospital.

BUTLER, W. HARRIS, M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for East Woolwich.

COLLINGWOOD, FREDERICK W., L.R.C.P.Lond., M.R.C.S., has been appointed Assistant House-Surgeon to the Torbay Hospital, Torquay.

CUSSE, ERNEST, M.R.C.S., L.S.A., has been appointed Resident Medical Officer and Secretary to the Bournemouth Cottage Hospital and Dispensary, vice T. G. Parrott, M.R.C.S., L.R.C.P.Lond., resigned.

DOVE, AUGUSTUS CHARLES, M.B., M.R.C.S., has been appointed Junior House-Surgeon to the Cancer Hospital, Brompton.

GUTHRIE, LEONARD L., M.A., M.R.C.S., L.S.A., has been appointed House-Surgeon to Paddington-green Children's Hospital, vice Dr. George Parker.

HASLEWOOD, ALBERT, M.R.C.S., has been appointed Honorary Medical Officer to the Devonshire Hospital, vice W. H. Flint, L.R.C.P., resigned.

PARROTT, THOMAS GODFREY, M.R.C.S., L.R.C.P. Lond., has been appointed Resident Medical Officer to the National Sanatorium for Consumption and Diseases of the Chest, Bournemouth, vice Dr. Humby, resigned.

WELSFORD, GEORGE FREDERIC, M.B.Cantab., M.R.C.S., has been appointed Medical Officer for the Second District of the Woodstock Union.

Births, Marriages, and Deaths.

BIRTHS.

ARNOTT.—On the 3rd inst., at Burnswark, Malabar-hill, Bombay, the wife of Surgeon-Major James Arnott, M.D., of a son.

BATTYE.—On the 27th ult., at Denbigh-street, the wife of John Howard Battye, M.D., of a son.

COHEN.—On the 2nd inst., at Stranraer-place, Maida-vale, W., the wife of A. Cohen, M.A., M.D., of a daughter.

CONSTABLE.—On the 29th ult., at Kennington-park-road, the wife of Joseph J. Caffry Constable, M.D., of a daughter.

DALE.—On the 24th ult., at Park Lea, Scarborough, the wife of Frederic Dale, M.D.Cantab., F.R.C.S.Eng., of a son.

DUKES.—On the 1st inst., at Sunnyside, Rugby, the wife of Clement Dukes, M.D.Lond., of a son.

HEDLEY.—On the 29th ult., at Lawn-road, the wife of Brigade-Surgeon W. S. Hedley, M.D. (retired), of a son.

LITHGOW.—On the 2nd inst., the wife of T. G. Lithgow, F.R.C.S.Ed., L.R.C.P.Lond., of Stirling House, Farnborough, Hants, of a son.

MACLACHLAN.—On the 28th ult., at Fenwich, Thurlow-park-road, West Dulwich, the wife of Andrew MacLachlan, M.D., of a son.

ROBINS.—On the 4th inst., at Down Hall, Rippingale, Bourne, the wife of G. Norman Robins, L.R.C.P., M.R.C.S., of a daughter.

MARRIAGES.

BASS—BISHOP.—On the 29th ult., at St. John Baptist's, Crowthorne, Berks, Charles William Bass, M.R.C.S., of Langsett, Ilford, Essex, to Edith Mary, eldest daughter of George Bishop, of Wellington College, Berks.

BROWNE—GARRETT-SMITH.—On the 30th ult., at St. Mark's, Hamilton-terrace, James W. Browne, M.A., M.B., Fellow of Worcester College, Oxford, to Alice, younger daughter of J. W. Garrett-Smith, of Abercorn-place, N.W.

PAGE—GRACE.—On the 27th ult., at Downend, G. Shepley Page, L.R.C.P., L.R.C.S.E., to Katharine Fanny, second daughter of Henry Grace, of Kingswood-hill, Bristol.

SMALL—HALL.—On Aug. 17th, at St. Philip's Church, Sydney, N.S.W., John Small, L.R.C.S.Ed., L.R.C.P.Ed., of Geelong, Victoria, to Alice Maud, second daughter of the late Capt. R. Morgan Hall, of 48th and 13th Regiments, Bath, England.

WATSON—GREY.—On the 29th ult., at Newport, Isle of Wight, John Watson, M.D., of Royal Heath, Sandown, Isle of Wight, to the Lady Anna Tredger, youngest daughter of the late Rev. Harry Grey.

DEATHS.

ASHMEAD.—On the 4th inst., at Talbot House, Brierley-hill, Helen Wilhelmina Ashmead, the beloved wife of Geo. Ashmead, L.R.C.P.Ed., L.R.C.S.Ed., and youngest daughter of the late Captain Henry Walker, of Castle Stuart, Inverness-shire. Deeply regretted.

PEARCE.—On the 1st inst., at Eastbourne, George Pearce, M.D., of Leicester, aged 47.

SEATON.—On the 30th ult., at Hallifford House, Sunbury-on-Thames, Joseph Seaton, M.D., F.R.C.P., F.R.G.S.

SHIRREFF.—On the 28th ult., at Sowdon Lodge, Lympston, South Devon, James Hales Shirreff, M.D., aged 73.

WATSON.—On the 28th ult., John Ferra Watson, J.P., M.R.C.S., of Heigham Hall, Norwich, aged 69.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

THE ELECTION OF DIRECT REPRESENTATIVES.

AT the moment of going to press we have received advertisements with reference to the approaching election of Direct Representatives from the President of the Medical Council, who, for this purpose, is the returning officer. All nomination papers must be forwarded on or before Nov. 9th to the Registrars of the Branch Council of England, Scotland, and Ireland respectively.

G.—We do not prescribe.

TONSILLITIS AND ITS RELATION TO SCARLATINA AND DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—I am glad to find from Dr. Hingston Fox's letter that we are not so much at variance as at first sight appeared. That all cases of tonsillitis are not due to infection may, I think, be argued from the facts that some people are subject to constantly recurring attacks, and the severity of each is in no degree less severe than the preceding one. Then, too, there are some cases of tonsillitis accompanied with ulceration of the surface which, if treated with iron and quinine, go on from bad to worse, and yet rapidly improve under the effervescing citrate of potash. Now, were the ulceration due to septic poisoning, the very reverse of this would occur; and I therefore consider that the ulceration in these cases is dependent upon extreme distension of the surface of the gland tissue. Again, I may state that I and my family, though resident in different places, were at one time frequent sufferers from quinsy; and even now, were I to undergo excessive fatigue for a week or two and take my meals irregularly, I could easily bring on an attack. Never have I seen albuminuria or paralysis follow an uncomplicated case of quinsy, though one of the latter, it appears, was reported the other day by Dr. Prévost in the *Archives Médicales Belges*; and I have never known two cases to occur in the same house within three or four, and I think I may say with perfect correctness six, months of each other. In fact, I have never had a single case which could be said to arise from infection or contagion.

I am, Sir, your obedient servant,

Surbiton, Sept. 30th, 1886. F. P. ATKINSON.

P.S.—It appears to me that Dr. C. Haig-Brown has somewhat mixed up simple inflammation of the tonsils with the follicular type of the disease; though, in my opinion, they are entirely different as regards their origin. The former is generally accompanied with enlargement and tenderness of the submaxillary gland or glands, the latter with enlargement and tenderness of the lymphatics.

A MONSTROSITY.

THE thirty-ninth number of the *Gazette Hebdomadaire des Sciences Médicales* contains two figures and descriptive text of a so-called cyclocephalic monster. The chief feature in the monster is the want of development of the nasal region, attended with the approachment of the two orbits, so that they have become partially fused. A further degree of this deformity leads to the complete fusion or want of differentiation between the two orbital regions, and there is then but one organ of vision. In the specimen in question there was a rudimentary nasal appendage which formed a kind of flap that partially concealed the abnormal orbital region.

A Twenty-five Years' Subscriber.—1. We consider our correspondent was not properly treated by the coroner if that gentleman made the remarks attributed to him with the knowledge that our correspondent had been ordered to discontinue his attendance upon the deceased.—2. The remarks no doubt have a tendency to damage our correspondent's practice; but they are, of course, not actionable. Moreover, our correspondent's reputation is quite good enough to warrant him in treating the matter as beneath further notice.—3. We would not advise petitioning the Secretary of State.

Berkshire.—Probably next week.

"A CASE OF GUINEA-WORM."

To the Editor of THE LANCET.

SIR,—Your correspondent, "Reader," who seeks advice as to the treatment of a case of guinea-worm in your last issue, should take a piece of sticking-plaster about an inch and a half wide, and roll it tightly up to about the calibre of a No. 6 catheter, allowing the free edge of the plaster after cutting to the proper size to remain unrolled for the width of about half an inch. The protruding end of the worm (head end) having been first wiped dry by a dab from a sponge or carbolised cotton over it, and the sore whence it issues, and the little roll of plaster above referred to having been placed transversely beneath the worm and over the healthy skin beyond the point of exit, is placed across in regard to the long axis of the little spindle, and between the free surface of the rolled up piece of plaster, which are then closed over it and all firmly secured together. The little spindle is then taken hold of tightly at both ends by the thumb and forefinger of both hands, and most gently turned round underhanded, strictly on its own axis, so as not to drag, till a coil of the worm is wound around it, and is then secured *in situ* by means of a few narrow pieces of strapping. No attempt must be made to extract the worm at one sitting, or failure is sure to follow, and a gentle continuous traction and tension on the worm is only admissible, on which entirely will depend the successful issue. Should any spasmodic or undue strain be put on the worm it may break, as it is often rather friable, giving exit to acrid exudations and infiltration into neighbouring tissues, followed by severe local inflammation and irritation. As the worm often attains the length of some feet, and always several inches, I need not say that it will take some days, or weeks, to effectually get rid of it. The spindle need not be changed throughout the whole process; but it, and the little sore, must be kept well cleansed at each daily sitting with a weak solution of carbolic acid. It is quite obvious that the plaster spindle is much more pliable than ivory or any other solid material, and adapts itself to any irregularities of surface from which the worm often issues, and can be kept firmly *in situ*, without unrolling, by a little strapping, and without causing any undue strain on the worm. The watchwords must be *gentleness*, *patience*, and *time*. The patient, of course, must be kept quiet during the treatment.

I am, Sir, yours faithfully,

Truro, Oct. 5th, 1886. D. W. WILLIAMS, M.D.

W. E. (Belfast).—Perhaps the fullest and best treatise on cremation is that recently published by Professor Carlo Cucca of Naples. Of the various kinds of "ustrina," or "crematoria" (as they are less accurately called), he compares those of Polli, of Gorini, and of Siemens, and pronounces in favour of the last-named as not only the best, but the cheapest. He declares that cremation, instead of being optional (*facoltativo*) should be made obligatory in Italy.

Mr. Startin.—Yes, in an early number.

FEES FOR NECROPSY IN THE ISLE OF MAN.

To the Editor of THE LANCET.

SIR,—I notice in your issue of Saturday, Sept. 25th, a paragraph to this effect: "The Governor of the Isle of Man, it is reported, has reduced the fee of £1 1*s.* for a post-mortem examination by order of the coroner to sixteen shillings." I am in a position to state that the report is incorrect. His Excellency has not reduced the fees, but rather increased them. Formerly the payment made for medical evidence before the coroner was 10*s.* 6*d.*, and the fee to which the medical man was entitled for a post-mortem examination and for the evidence arising therefrom, if such evidence were given, was £1 11*s.* 6*d.*; or in all, £2 2*s.* Now the payment is to be, for evidence before the coroner, 15*s.* 6*d.*, and for a post-mortem examination and evidence arising therefrom, £1 11*s.* 6*d.*; in all, £2 7*s.* I think it but right that these facts should be made public. I am, Sir, yours faithfully,

Douglas, Isle of Man, Oct. 4th, 1886. J. A. DEARDEN.

A DEFENCE OF TEA.

AN article which appeared in our columns some weeks ago condemning the excessive use of tea as injurious has come under the observation of the Chinese at Shanghai; and a recent copy of the *Shên Pao*, a local native paper, contains a leading article which is evidently founded upon a misconception of the tenour of our remarks. The writer states that for several hundred years no one has heard that the habit of tea drinking is an injurious one. Why should it suddenly become so to-day? Moreover, tea has been drunk in China for thousands of years without any apparent ill-effects. Our contemporary then proceeds gravely to discuss the various sources from which this imagined danger may arise. The water cannot, it argues, be injurious, for it has been boiled; and as adulteration of the leaves has practically ceased, how can the pure article be injurious when the adulterated article which was exported and consumed for years had no evil effects? Another reason for the appearance of the article condemning tea has been suggested to the contributor to our contemporary; and although in his opinion it is not deserving of immediate and implicit belief, yet, looking at all sides of the question, he would not venture positively to state that it is devoid of truth. "It is said that a foreign doctor discovered a spring of water possessing valuable medicinal properties, and that after mixing some kind of preparation with it he put it up in bottles, like the lemonade and soda-water used by foreigners here; that as the demand was not very brisk, he originated this story about the injurious properties of tea, with a view of increasing the sale of his preparation." Despite, however, such a low estimate of the honour of foreign medical men, the writer concludes with the expression of high admiration for their professional skill, which he contrasts with that possessed by the native faculty much to the latter's disadvantage.

M.B. will have to obtain leave to practise in Spain. This may be granted to an English graduate without examination, but cannot be claimed as a right. We are making further inquiries, and will endeavour to answer our correspondent's query more fully in a subsequent issue.

Mr. Greenwood (Stronafyne).—There are several institutions of the kind, for a list of which we must refer our correspondent to the Charities Register, published by Longmans.

A NEW METHOD OF ARTIFICIAL RESPIRATION IN CHILDREN.

To the Editor of THE LANCET.

SIR,—For several years I have adopted a very simple method of performing the artificial respiration that is sometimes required in new-born infants, and as it is devoid of the display usually attending the present plan, which is sometimes so exciting to nervously constituted mothers, perhaps it will commend itself to many of your readers.

The child is laid in the supine position; the palm of each hand of the operator is placed on each side of the chest, with the nipples underneath the hands and the fingers overlapping the ribs and partly covering the abdomen. For inspiration the fingers are bent so as to catch under the free edge of the ribs, in order to raise the chest wall outwards and upwards, whilst for expiration the fingers are extended and pressed together with the palms of the hands on the chest and abdomen. Trusting this explanation is sufficiently lucid,

Believe me, Sir, yours faithfully,

Bournemouth, Oct. 1st, 1886. F. W. CORY.

Medicus (Sunnyland) will be obliged to pass the examination for the State diploma in order to practise in Switzerland. His best plan will be to write to the Dean of the Faculty of Medicine at Geneva.

Volo.—Our correspondent has a legal claim. Such claims have been allowed. Whether in any given case they will be recognised, or it is worth while to spend money and worry over them, is a matter for grave consideration.

A Beginner.—Roscoe and Grainger Stewart.

SOMETHING WRONG AT THE "COLINDERIES."

To the Editor of THE LANCET.

SIR,—I have just been made aware of a disgraceful state of things at the Exhibition at South Kensington. One of the *employées* informs me that since it was opened they have had to pay for the use of the waiting-rooms. Do you not think this is a very cruel arrangement? The poor girls are at their duties twelve hours each day. Some come from a distance, so that fourteen hours per day is about the average they are absent from home. They are charged a halfpenny each time they visit the room. To be healthy and comfortable 3*d.* per day is needed—1*s.* 6*d.* deducted from 12*s.* per week! Naturally, economy is practised. Consequently much misery is endured, and no doubt in many cases the foundation laid for painful diseases.—I am, Sir, obediently yours,

Sept. 30th, 1886. E. M.

SEVERAL articles and communications have been crowded out of our present number; amongst them being an editorial on the introductory lectures delivered at the opening of the several medical schools, annotations on various subjects, letters from numerous correspondents, &c.

Medical Diary for the ensuing Week.

Monday, October 11.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
PARKES MUSEUM OF HYGIENE.—8 P.M. Mr. Gordon Smith: Sanitary Appliances.

Tuesday, October 12.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Wednesday, October 13.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Tuesdays and Fridays, 9.30 A.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.: and Saturday, 1 P.M.
ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Mr. T. B. Rosseter: Trichodina as an Endoparasite; Desiccation of Rotifers; The Abbe-Zeiss New Objectives and Eyepieces.
HUNTERIAN SOCIETY.—8 P.M. Mr. Hutchinson: On the Value and Measuring of certain Symptoms.
PARKES MUSEUM OF HYGIENE.—8 P.M. Prof. F. De Chaumont: Ventilation, Measurement of Cubic Space, &c.
BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Dr. Meadows: Cæsarean Section.—Mr. Lawson Tait: Extra-peritoneal Cysts. Specimens will be shown by Dr. Edis, Dr. Fancourt Barnes, and others.

Thursday, October 14.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Friday, October 15.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
SOCIETY OF MEDICAL OFFICERS OF HEALTH.—7.30 P.M. Dr. Alfred Hill (President): A Consideration of the Various Modes of House-refuse and Sewage Disposal.
PARKES MUSEUM OF HYGIENE.—8 P.M. Mr. Percy Boulnois: Scavenging and Disposal of Refuse.

Saturday, October 15.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year	£1 12 6	Six Months	£0 16 3
To CHINA AND INDIA		One Year	1 16 10
To THE CONTINENT, COLONIES, AND UNITED STATES		Ditto	1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

Introductory Address
ON
MYSTICISM, SCEPTICISM, AND MATERIALISM IN MEDICINE.

Delivered at St. Mary's Hospital, Oct. 1st, 1886,

BY MALCOLM MORRIS, F.R.C.S. ED.,
SURGEON TO THE SKIN DEPARTMENT.

GENTLEMEN,—The frequent and regular recurrence of events tends to produce indifference as to their nature and origin. As with the words of a language, so with the customs of a country—the original meaning is often lost in obscurity. Inaugural lectures form no exception to this result of time. So accustomed have we become to them, so gradual has been their development, so strong is their family likeness, that they are in some danger of becoming meaningless ceremonies. The introductory lecture is bequeathed to us by a bygone age. It comes to us as a curious academical heirloom, venerable with associations. In spite of a troubled past, it has retained much of its early peculiarity amid more than one revolution in the educational world. Little wonder that the initial purpose of this traditional form should have become obscure, and its original outline a little blurred.

It may, then, not be out of place to ask the purport of this now familiar ceremony? Its simple aim is to introduce the beginner to the study of medicine. In this sense it is clear such a lecture would be impossible at the present time. Its ambition would be beyond the scope of human capacity. One hour's discourse would hardly serve for the introduction of the student to a science that is one of the most complex and diffuse in the realm of learning. The ideal initiatory lecture was only possible at a time when that science was one of vague and narrow scope. In proportion as it has grown, the formulæ which once sufficed to introduce it have become dwarfed and inefficient. They have assumed the form of vehicles for advice, or have served to embody a few of the prevailing opinions of the time, or have been used to chronicle progress and to record experience, or to vaunt the all-importance of a particular school. Considered as the first of a series of technical dissertations they have ceased to exist. I feel, then, that I need not apologise for not attempting an impossible task; while, on the other hand, I must ask your indulgence for an effort that must needs be halting and imperfect. In the place of endeavouring to introduce the uninitiated to the entire science of medicine, I would venture to draw your attention this afternoon to certain historic phases of the modern art of healing that appear to me to demand consideration. A review of the aspects of medicine will serve, I hope, as an introduction rather to its environment than to its details. Instead of attempting a geological survey, so to speak, of the scientific planet itself, I will confine myself to an examination of the atmosphere in which it revolves. The first point to which I would direct your attention concerns the element of

MYSTICISM IN MEDICINE.

Could Lord Macaulay's New Zealander enter this assembly, he would be puzzled to recognise our business as that of the initiation of men into a knowledge of the processes of life and death. Medicine and mystery are with him interchangeable terms, and he would miss the incantation, the weird dance, and all the saturnalia that are for him the natural concomitants of the healing art. Noise, panic, and mystery are the three accessories of aboriginal medicine. The "medicine man" is a protoplasmic element in evolution—a primitive admixture of the charlatan, the fanatic, and the mountebank. He is, nevertheless, the germ from which, as a profession, we must acknowledge descent—our prototype in an age when science was but a slender figure arrayed in the too exuberant drapery of mysticism. Onward a century or so, we encounter this same germ developing into the physician of the middle ages—a gloomy compound of ignorance and superstition. He is still deeply mysterious, but there is in his art less of falsehood, more of truth, albeit he dabbles in spells and occult influences. He seeks to impress the common mind by means of mystic crucibles, and works hand-in-hand with the astrologer and the magician. But he is withal less of the quack, and more of the student of science. There is an earnestness in his unwearied search for the elixir of life, and some reality in his pursuit of the philosopher's stone. His room, exhaling the vapours of an unknown world, must have been a very den of terror. Yet to-day his grandest phenomena are eclipsed by the most unpretending conjuror. Still, this element of mystery was not wholly unproductive of good. It saved the life of science when threatened by a bitter fanaticism. Its spark was fanned by the love of greed when it had ceased to be maintained by the love of knowledge. At the risk of liberty and life the scientist toiled on in anxious seclusion, fearful himself and yet inspiring fear by reason of the exalted nature of the pretended objects of his researches. His was a position of great power, though the true spirit of scientific medicine was in the feebleness of infancy. Nearer to our own time is the period when with an increase of knowledge there came a decrease of mysticism. The supernatural was not quite abandoned, but a more tangible foundation for true learning was arising from the study of human anatomy. At this period was propounded the mystery of the humours of the body, the lymphatic, splenetic, and the like. The condition of the patient was said to be dependent on an admixture of these or the predominance of one of them, and it was the physician's work to endeavour to remove or to modify these humours. The belief in drugs was at its zenith; the examples of the old formulæ then employed that still survive are permanent evidences of human credulity.

Two questions naturally arise out of these considerations: First, How was the mystic element evolved? and, secondly, Has it entirely disappeared from the enlightened medicine of our own time? I think it will be found that the element of mysticism in medicine has been forced upon it by the public. It is the result of two opposing conditions—the absolute knowledge demanded by the laity on the one hand, and the more or less extensive ignorance of the professor of the healing art on the other. This ignorance, where it exists, he must not acknowledge. He is expected to be able to recognise disease and to know how to treat it. Yet no other professor is so "cribbed, cabined, and confined." The astronomer may admit want of knowledge. The chemist and the physicist may say, "*This* I know, *that* I do not know"; and the lawyer may, without loss of reputation, confess himself an agnostic in matters legal. But such an admission would be fatal from the lips of a medical man. With him nothing must be admitted that would disturb that most potent factor in therapeutics—absolute and implicit faith. Medicine, despite the strides it has made in modern times, is still extremely defective. This scanty lore must be supplemented by fiction. The public insists upon absolute knowledge. This cannot be obtained; it must therefore be invented. Had the public in the middle ages been content with the little learning the period afforded, the student would have been saved many volumes of nonsense, and the sick man a flood of obnoxious medicine. But they were insatiate, and would not be satisfied with a little. The phenomena of disease became associated with star influence, spirit agency and other dim powers. That in some directions this mysticism did much harm to science cannot be doubted, but happily its influence was not wholly paralysing. It gave at least a spurious dignity to the pursuit of knowledge at a time when the sum of human knowledge was by no means great. It offered attractions to aspiring men, whose imagination it stimulated; while it stifled in many ways the true spirit of scientific inquiry, it became a tempting lure to many in whose brains that spirit was quickening. It saved learning at a time when it was fast sinking into contempt, and it floated the little ark of science over a troubled and tempestuous sea.

And there is mysticism in the medicine of to-day. Athwart our paths may still be traced the track of the astrologer. There remains in the people a belief in the efficacy of drugs as drugs—a belief that as for every bane there must be an antidote, so for every disease there must be a curative leaf or root. Nature is distrusted; disease is still represented as some evil influence to be exorcised. In the popular mind disease walks the earth as a devouring fiend, and has a personality about it as of old. Our very phrases, "Stricken with disease," "Visitations," and "Seizures," are survivals of the conceptions of primitive times. There is still to-day a demand for

Digitized by Google

perfect knowledge from all professors of the healing art, and, as of old, the gaps in medical science—which is far from having reached the category of the exact—have to be filled with fiction, though less, it is true, in amount, and less unwholesome also in character. The mysticism survives in the courtly phrase and the ambiguous language of the practitioner of modern times. When sorely pressed by the sick man, the physician's only armoury is equivocation, from which he draws such verbal weapons as "the state of the constitution," "the tone of the body," "the general health," "lowered vitality," and *id genus omne*—a vicious circle of ambiguous platitudes, diluted to vagueness by the admixture of scientific terms. Are not these in some sort a survival of the circle of the horoscope? This antagonism between the public and professional mind is deplorable. It cripples investigation; it places the medical man in a false position, in which his dealings become artificial and his utterances evasive. At no far distant day, however, there is hope that medicine will have shed for ever the last vestige of mysticism, and what will rid it of such unworthy disguise will be the influence of a more carefully educated public. A great step in this direction is already being accomplished by the introduction of the elements of physiology and the laws of health as essential features in scholastic training. This knowledge is precisely what is wanted to qualify an individual to form a true estimate of the relations that should exist between the medical man and the patient. With a mind cleared of the crude absurdities in which his forefathers blindly confided, he will be of all men best able to appreciate the difficulties of the doctor and to be tolerant of his deficiencies. He will understand how to be satisfied with the known, without vainly clamouring for the unknowable.

SCEPTICISM IN MEDICINE.

Let me now invite your attention to what I may term the element of scepticism in medicine, an influence which will probably have no small share in moulding the medical man of the future. Intellectual development has been the most prominent feature of the present age. Both in extent and variety the attainments of science and of art have been prodigious. Examples are not far to seek. Down to the commencement of the present century the advance made in so simple a branch of practical mechanics as locomotion was altogether trifling. The revolution effected by the introduction of steam as a motive power was a revolution indeed! The adaptation of steam to this end gave an impetus to inventive genius that enabled it at one bound to outstrip the puny efforts of past ages of the world. The scientific step from the primitive chariot of ancient times to the stage-coach was wholly insignificant by the side of the great advance which will for ever be associated with the name of Stephenson. This result was not the work of centuries. The whole of the vast revolution was conceived and perfected in the lifetime of an individual man. In the art of lighting, the process of development was hardly less startling and sudden. All that the knowledge of ages had done in that direction was but a trifle in comparison to the introduction of gas. Here, too, the entire change has been effected within the limits of one generation; indeed, within the recollection of, I daresay, more than one here present to day. And what a host of other marvels does this period include. Picture the world before the introduction of the telegraph. We can hardly realise the fact that there has been a period within the memory of living man when yet it was not. Its coming united humanity into one family. It was the one touch of science that made the whole world kin. Electric force is to-day one of the main bonds of our civilisation. It is difficult to imagine that these advances in science have been made since this century opened. In every direction we see indications of the same marvellous activity of thought. We see the various departments of science combining for mutual benefit, working harmoniously, and producing unexpected results. And even more stupendous have been the movements in the philosophical world. It is not too much to assert that the Darwinian theory invested our very existence with a new meaning. It was a revelation that startled the whole civilised world. It shed a light on the science of life that necessitated the re-writing of its history, destroying at a blow many previous systems of thought. Something of a like revolution took place in mental philosophy, in the study of the human intellect, and the analysis of the human emotions, on the introduction of the anatomical element. Before this our conception of mental movement was shadowy and unsubstantial. Anatomy lifted many obscure questions into the light of day. It has already given us the key to many mysteries of the mind, laid bare many secrets of the senses, and has provided a basis for the solution of matters that are still impenetrable.

Our age is one of tumultuous mental activity. Old forms of belief are on all sides being assailed; primeval faiths are crumbling to decay. The philosophy of the past is either dead or dying. Old things are passing away; a host of ancient prejudices are tottering to their fall; and such is the rapidity with which we are moving, that scarcely have they been levelled with the dust when new creeds spring vigorously from their ruins. Such are the times in which we live, and they are times in the highest degree favourable to scepticism. It is rampant among us at this moment. Speculation is rife, and it is a blemish which medicine has not escaped. Scepticism has infected medicine fully as much as it has religion. Where to-day is the implicit belief in drugs which was a dogma of the healing art in past times? Like many another faith venerable and unquestioned by our forefathers, it is losing or has lost its hold upon men's minds. The extreme sceptic boldly avows his entire disbelief in the potency of any drug whatever; others less dogmatic content themselves with acknowledging the value of a drug or two. The position is attained where scepticism, wrapped in its own self-confidence, once and for all repudiates all aids and accessories; briefly, it states its deliberate opinion that disease is infinitely better left to itself. The natural physiological energy of the body is the prime element in the healing process. This is neither more nor less than modern fatalism—waiting on events. Such a doctrine, if successful, would be fatal to medicine. Without doubt the element of interference has been far too prominent in the past. But there are absolutely no just grounds for rushing to the opposite extreme and forswearing the use of remedies merely because they have once been administered in gross excess. The remedy is as bad as the disease.

There is no use in blinking the fact: young men are and always will be naturally attracted by scepticism. There is about it a sensational fascination congenial to the developing and active mind. It is a bias, however, most vigorously to be withstood. Scepticism as such is too often adopted as the alternative to careful reasoning and the patient examination of facts. In training the intellect, the student will find it advantageous to cultivate that form of it which is the chief characteristic of the judicial mind. A judge's duty is twofold. It is not sufficient that he shall be able to arrive at a just decision upon the facts *presented* for his consideration; he has, in the first instance, also to decide what facts are admissible as evidence. On these and on these alone must his final judgment be based. The rules of evidence are known to every advocate, but, having the whole case to handle, he cannot devote so much attention to the question of the acceptance or rejection of this or that evidence as can the judge who is less hampered with details. Like the judge, we have not only to sift that which is given us, but to watch and to seek out whence it comes, and to look to it lest any who may have pet theories to support may find us so-called facts to fit them. Special pleaders are by no means monopolised by the bar.

Changes of belief irresistibly forced upon a man by the accumulation of facts and the weight of well-stored experience are worthy of all respect and consideration. But many forms of scepticism in modern medicine are rather to be deemed emotional and infective, and as such are apt to take possession of the learner, who will be tempted to accept his creed upon judgments other than his own. Whatever we profess, whatever we deny, let us see to it that we are able to give "a reason for the faith that is in us," and that reason is at least our very own.

So much for the elements of mysticism and scepticism. Let me now ask your patience a few moments while I refer to the third aspect of my subject.

MATERIALISM IN MEDICINE.

Materialism must be viewed as a useful and indispensable feature in the study of medicine. It was the absence of this element as a firm basis and starting-point that was mainly productive of the mischievous results we have considered under the head of mysticism. We have seen how medical science suffered at the hands of the alchemist and astrologer: can we be quite sure that it is in no like danger from the well-intentioned but too restricted efforts of the materialist? The mind requires a field neither too large nor too small. Formerly, the tiny light of science wasted all its

Digitized by Google

rays in the vain attempt to illumine regions far beyond its ken. The result was mysticism. To-day materialism threatens to err almost as much in the opposite direction by throwing all the little light it can command upon a pin's point. The man of science in the middle ages lifted his rushlight to the skies, and, soaring, lost its glimmering aid. In our own time he stoops so low as practically to hide its light beneath a bushel. While we are minutely inspecting matter as matter, we are narrowing our vision, and shutting out the broad issues which must be read with it, if we would rightly comprehend those enigmas of life to which matter affords the only key. While we minutely analyse the details, our eyes are out of focus for the broad truths the sum of them should teach us. Medicine should attempt not only to acquire facts, to accurately record phenomena, to compare kindred appearances: but it must go a step further and strive to grasp their wider significance, their general bearing. Many questions have been practically shelved, because men have become absorbed in the process of grubbing over a few minute details. The mind has been led away from a right conception of the whole by a too minute consideration of the part. In saying this, I would not be understood to disparage the practice of fact accumulation. It is of incalculable value as a means to an end. All honour to those whose lives have been devoted to a work so arduous, so unattractive. But in modern medicine we are apt to make too much of a fact *per se*. Let us have a care that in moulding the medicine of the future the constructive power claims its due and proper share of our consideration. At present the process is one rather of disintegration. Disease is being studied almost exclusively in regard to its minutest issues. We happen at this moment to be greatly concerned in the microscopic investigation of disease, having traced its source, as is confidently asserted, to bacteria. The inquiry, which is undoubtedly a most valuable one, is absorbing the genius of the time. Time was when that fatal scourge, consumption, was attributed to certain humours in the blood. Further investigation led to the conclusion that it owed its origin to a small particle—the tubercle. And now, in our own time, scientific inquirers have pushed their inquiries to such an extent that the most minute living particle known is reputed to be the parent of this fell disease. There is something uncanny in the contemplation of this minute organism. It may be almost taken to represent the limit of philosophical inquiry. But wonderful as the discovery is, do we know any more concerning the disease itself? Do we save more lives than did our forefathers? This is the crucial question which should be the touchstone whereby to measure our success. In the examination of disease, it must not be supposed that all truth lies at the bottom of the microscope, any more than at the bottom of the proverbial well. While men were worshipping facts as facts, Darwin was busy constructing his great theory. Facts were the basis upon which he built his grand superstructure; but no amount of unreflective pursuit of mere detail, however persistent, would have given the world the Darwinian theory. I say, then, and I would urge it strongly, that pure materialism in medicine may be carried to an injurious extreme. In modern pathology, for example, as originated by the German school and taught by its apostles, while men are actively contesting as to the nature or formation of a certain cell—whether it be spindle-shaped, round, or ovoid; whether it be derived from this tissue or from that—they are likely to lose sight of the real bearings of the case. By all means respect facts, and you cannot better show respect for them than by using them. A medical inquirer is not a mere collector. Collect your facts, and then reason from the data you have established. A collection teaches nothing till it has been arranged. The tendency at present is, in the majority of instances, to collect everything and to arrange, and therefore to adduce nothing.

One last word—and I speak now as a student to students. I have done my best, in an imperfect way, to point out what I conceive to be some of the dangers that surround the study of medicine. I would warn you to avoid the mystic on the one hand, and the sceptic and materialist on the other. But while I have been suggesting what not to do, you must understand that progress cannot result from negations. There is one condition upon which your success will in the main depend. Without this your efforts must be abortive. I refer to the oft-quoted but little-heeded precept—"Work for work's sake." The days of *walking* the hospital are over; it is now *working in* the hospital. You have a hospital and school wherein to work of which you may justly be proud. And you have in our Dean an example of energy and perseverance which you may well imitate. It is to Mr. Field that we are chiefly indebted for our present position among the metropolitan schools. You are entering a serious and earnest profession. Medicine is a goddess that brooks no divided worship. She will have all your faculties or none. She demands an actual sacrifice—a complete devotion to duty without adequate reward. This is the true diploma of medicine, and without it we cannot consider ourselves to be qualified. Medicine is noble just so far as it is unselfish. Clearly understand that you are entering upon a career in which work is inadequately paid, honours are few, and the struggle for existence keen and constant. But, in spite of this, there is something in the contact with disease that stimulates even the most prosaic, and that something is best told in words uttered forty years ago on a similar occasion to the present by Sir James (then Mr.) Paget. "There is not," said he, "in this world a nobler spectacle than that of a rational being devoting himself with patient, earnest perseverance to the cultivation of his powers, that they may be employed in the discharge of duty. Knowing that a force within him is capable of unlimited expansion, and confessing in his inmost consciousness that its development and its exercise are duties of strongest obligation, he pauses not to ask whether outward reward will crown his work or not; much less, with scrupulous calculation, does he count the cost and gain. But, because he knows that the powers and opportunities he has received were given him for use, he resolves that not one of them shall run waste or wild: for him to be indolent were to be unthankful. And so, in toil, yet not in weariness, he pursues his way; sowing seed, of which he reckons not whether he shall reap the fruit; content, because he is in the path of duty; blest, if only he may see or think that he ministers to the welfare of his fellow-men." It is to this toil that we bid you welcome to-day.

There is on all sides a constant cry for rest. Let not this cry be heard during your few years of study. Remember well the solemn words of Arnauld—"Rest? rest? Shall I not have all Eternity to rest in?" The life you must look forward to is one that can only stimulate the imagination of the strong man. A vast multitude of the practitioners of medicine die in harness. They die as they have lived. They never attain to that oasis of rest to which their long labours give them so earnest a claim. They are debarred the very peace they have been instrumental in bestowing upon others. And in many and many an instance they only find the long-sought-for rest when that time is reached of which Browning speaks—a time

> "When something like a white wave of the sea
> Breaks o'er the brain and buries us in sleep."

THE CONNEXION BETWEEN PULMONARY PHTHISIS AND OVARIAN DISEASE.

BY BEDFORD FENWICK, M.D., M.R.C.P.,
ASSISTANT-PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK, AND TO THE HOSPITAL FOR WOMEN, SOHO-SQUARE.

IN one of the most recent works upon the subject, the author[1] writes: "Of the causes of ovarian tumours nothing positive is known." But various observers have each adopted a pet theory to account for the production of these new growths. For example, Dr. Safford Lee[2] firmly believed that parturition created a tendency thereto. All the facts and figures, however, on which he based his belief would apply much more forcibly to prove that pregnancy was the active agency at work. While, on the other hand, it is most difficult to see how the mere emptying of the gravid uterus—an intrinsically natural process—could excite the slowly developing degenerative changes which more recent pathology has taught us takes place in these cases. Then Scanzoni taught that chlorosis, with its consequent amenorrhœa, was the great cause. But it is evident that this alone cannot possibly be the case, or the factory hands of London and our manufacturing centres would swell the numbers up to tens of thousands. Whereas, Sir Spencer Wells, in his classical work,[3] writes: "Calculations, based

[1] Peaslee on Ovarian Tumours, p. 86. [2] Ibid., p. 88.
[3] On Ovarian and Uterine Tumours, 1882, p. 244.

Digitized by Google

upon the Registrar-General's report, make it appear that the female population of England and Wales comprises an average of 11,000 cases of ovarian disease, with an estimated duration of life of four years each." And the above argument of the comparative infrequency of these growths would equally apply against another theory, that profuse menstruation and its consequent anæmia is the *fons et origo mali*. One more theorist condemns marriage, and yet another the state of single blessedness. But statistics show very little in support of either view. Of Sir Spencer Wells's 1000 cases, 569 were married and 431 were single—a fact which, considering the normal numbers in each condition, does not exhibit any marked preference on the part of the disease. Finally comes the question of pregnancy or sterility. Dr. Peaslee gives his whole and valuable support to the latter theory. Believing that the ovary needs rest as much as any other organ, he says that it is never at peace except during gestation and lactation, and that the ovaries, therefore, of a woman who has borne even one child have had probably eighteen months' rest out of thirty years' hard labour, while the organs of a childless case have never ceased from work. So he sums up the matter thus:[4] "It is the non-gratification of the instinct for procreation, and not the disappointment of mere sexual desire or of affection, which determines the result apparently in these cases." But the whole of his argument seems built upon the other theory: that the ovary, to keep healthy, must needs have rest from work. For my own part, I must confess that I fail to see that this necessity is proved. The lungs do not cease to fill and to empty, or the heart to contract and expand, till life itself is ended. We do not expect, or altogether desire, them to take a moment's rest. Why, then, should the ovary require eighteen months'? Bearing in mind the intimate, nervous, and vascular connexions between the ovary, the uterus, and the breast, it is at least easily to be understood why an increased hyperæmia and functional activity of either or both of the latter two organs should involve a comparative anæmia and inertia of the first-named. But even then we must always remember that it is by no means absolutely certain that during gestation and lactation the ovary necessarily obtains functional rest. Indeed, many well-known clinical and pathological facts would rather tend to prove that it does not do so. When, however, we look at the facts and figures of the theory—none of which, by the way, are furnished at first hand by Dr. Peaslee himself—we find the argument weaker still. "M. Boinnet states that out of 500 cases *collected by himself* (the italics are mine) he found that 390 had never borne children"[5]—that is to say, only about one woman in five in this unique series had been pregnant. Far be it for me to question the authenticity of these figures. I would only note that, as I have said, the series is unique. Then "M. Carlier has made the observation that cows which do not calve have ovarian cysts." The utter vagueness of this generalisation is rather bewildering. But it may be pointed out that, whatever may happen to cows, human females have been known to conceive and bring forth children while known to be suffering from cystic disease of one or both ovaries, and that most families have at least one member who has never conceived and yet has not been attacked by the disease in question. Now these apparently are all the facts, all the figures, all the arguments which have been brought forward to prove the theory that sterility is an exciting cause of ovarian cystoma, or, if I may so put it, that a passive negative state can excite an active positive degeneration. But, on the other hand, out of the 150 cases upon which this paper is based eighty had borne one or more children, seven had had one or more premature confinements, and only sixty-three of the whole number had never conceived at all. And, as I shall shortly show, these form a series of perfectly typical and unselected cases, so that in all probability they will represent the ordinary proportions of childbearing and childless cases of the disease. And, finally, if sterility by itself played any part in the production of ovarian cystoma, it is evident that the disease would be much more common than it already is in England, and, secondly, that it would be much more common still in other countries where the marriage-rate is lower and the birth-rate greatly less than in these islands. For example, the most recent statistics show that the population of Great Britain is doubling itself every sixty years, that of Germany and Austria together in every 110 years, and that of France in 140 years. But the rough figures which are obtainable on the subject from other countries would seem to show that ovarian disease is even less frequent abroad than at home. So that, however fallacious these figures may be, at least we may conclude that it is not a more usual affection among other European nations than our own. Consequently, I am led strongly to believe that sterility by itself has but little or no influence in the causation of cystic diseases of the ovary. It only remains, therefore, to consider the question of the influence of gestation; and, in the first place, I would recall attention to the normal physiological process which takes place in the Graafian follicle when impregnation of the lately-contained ovum has taken place. We know that, instead of the clot being absorbed and the follicle obliterated in a month, the process is so gradual that it is prolonged through the nine months of pregnancy, and even perhaps for a month or two afterwards. Is it not evident, therefore, how much greater is the possibility of the degeneration and liquefaction of the follicular contents during this greatly prolonged process of absorption than during the active obliteration of the sac begun and ended in one intermenstrual period? Pathologically, therefore, the probabilities are in favour of the theory that gestation may be an exciting cause of ovarian disease.

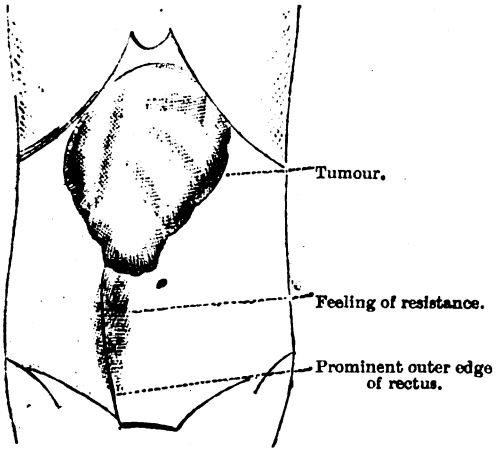
I deeply regret that Sir Spencer Wells does not afford us, in his work on the subject, the clear light which he throws upon any question which he has investigated. For I believe I am correct in saying that he has not given any authoritative decision upon the point of the causation of this disease. But out of the 150 cases which I have referred to, 87, as I said before, had been once or more pregnant, and only 27 of the remaining married cases had never been so at all. These figures, I frankly admit, are too limited to prove much; still, I think they tend to show that gestation may be a factor in the production of the disease. Then I would lay some stress upon the fact that so many patients date their illness from their last or some previous labour—a fact which so strongly impressed Dr. Churchill that he endeavoured to found upon it the theory that pregnancy was an exciting cause of the cystic growth. But it is only when labour has emptied the uterus that the patient notices the swelling of the abdomen, and the discomfort or pain produced by the tumour itself. And all who have had anything to do with these cases will recall how frequently a patient says that her first intimation of her complaint was that after a confinement her abdomen did not regain its natural contour, but remained more or less large and distended. In no fewer than eleven cases out of my series of 150 this fact had so impressed the patient that she succeeded, I find, in so impressing the clinical assistant that he made a special note of it. Of course I do not regard this question as settled by any means. We must have a great many more, and a great many more accurate, facts before the theory can be regarded as definitely proved. Still, I venture to believe that I have shown good and sufficient cause for drawing attention to its probability at least, and to the need for further investigation of the question. For if it be proved beyond cavil or doubt that gestation is an exciting cause of ovarian cystoma, the practical lesson as to prevention is plain, and important beyond measure.

There is yet another possible exciting cause which I have not seen specially noted, but which I am inclined to think is, perchance, more frequently the *fons et origo mali* than we at all suspect. I mean some accident giving rise to sudden hyperæmia of the ovary, and perhaps, through the consequent disturbance of its rhythm, to the commencement of the cystic degenerative change. Every clinical observer knows how often a fall or a strain is followed by ovarian pain or by hæmorrhage from the uterus, and how very often cases of ovarian prolapse or of chronic or subacute ovaritis are referred by the patient to some such accident when we investigate the history. And of the present series I find three well-marked cases in which the woman attributed her illness to a like cause. One, a married woman, aged forty-one, enjoyed good health till she was thrown from a cart. Great pain and swelling of the abdomen followed, and the latter slowly and steadily increased for five years when she came under treatment, and had a large ovarian cyst removed. Another, a single woman, aged twenty-four, fell downstairs and at once experienced great pain in the side, followed shortly afterwards by swelling, which gradually increased for eighteen months, when she was operated on for ovariotomy. I have heard of other cases where tumbling off a ladder or lifting a heavy weight was followed at once by abdominal pain and the formation gradually of an ovarian cyst, so that I must

[4] Op. cit., p. 86. [5] Op. cit., p. 89.

Digitized by Google

strongly express my belief that falls or severe strains may form an exciting cause of the disease. And now, briefly to review our progress so far, I have shown grounds for belief that gestation and accident may be potent exciting causes of cystic disease of the ovary, and that other theories which have been advanced do not bear rigid investigation.



(To be concluded.)

SOME REMARKS ON THE OPERATIVE TREATMENT OF CHRONIC OBSTRUCTION OF THE SMALL INTESTINE.

BY R. L. KNAGGS, M.A., B.C. CANTAB., F.R.C.S. ENG.

(Concluded from page 668.)

CASE 1.—F. M——, aged fifteen, was one of a family of eight, six of whom died young. He himself had had scarlet fever, measles, whooping-cough, and croup; but on April 15th, 1885, was quite well. On that day he stayed in a swimming bath two hours. The same night he was seized with shivering, and the next day had severe pain in the abdomen, which was so tender that he cringed at the slightest touch. On April 23rd he was admitted into the Fever Hospital for typhoid (?). The main features of his illness were at that time as follows:—(1) The pyrexia—never high, the highest point being 102·6°—lasted three weeks from admission; (2) the abdomen was distended; (3) there were no spots; (4) the bowels were never moved, except by enemata, until solid food was given, when they were opened naturally; (5) the child remained so thin when convalescing as to give rise to a suspicion of tubercle, but of this there seemed to be no very definite evidence. The boy left the Fever Hospital on July 4th, and a fortnight later began to have attacks of abdominal pain about the umbilicus, which "bent him double." In another fortnight vomiting set in, and he

would sometimes vomit his food, and bring up at one time "all that he had taken" for several days. Then a tumour, accompanied with pain and nausea, appeared at intervals in the upper part of the abdomen. Formed motions were passed daily till a week before admission to the infirmary, when they became fluid. Three months previously a little blood had been found in his motions. He had had a solid diet, and had lost a stone in weight during the previous six months.

On Jan. 29th, 1886, the boy was admitted into the Huddersfield Infirmary under my father's care. He was very emaciated and had a hectic flush. There was a distinct fulness both to the touch and the eye in the umbilical, epigastric, and both hypochondriac regions. The iliac regions were hollowed out, the spines being very prominent. The abdomen was resonant all over. After short palpation a prominent tumour appeared in the upper part of the abdomen, and active peristalsis of the distended intestines was plainly seen. This was accompanied by considerable pain, nausea, and gurgling. The shape of the abdomen was quite altered by the tumour, which stood out to the extent of two or three inches and disappeared after lasting a minute; it occupied the position shown in the above diagram. Under chloroform a feeling of resistance that had been noticed running from the inferior limits of the tumour towards Poupart's ligament resolved itself into the sharp outer edge of the right rectus, beneath which was something that felt like a length or coil of intestine containing some doughy material. The rectum was quite empty, but considerable resistance was felt upwards and to the right. Specific gravity of urine 1020; no albumen. The following treatment was adopted:—A quarter of a grain of extract of belladonna, in form of pill, three times a day, belladonna ointment applied to the abdomen, and a diet of peptonised milk only.

Fluid motions continuing to pass, and the boy's condition remaining unaltered, it was decided, after consultation, to explore the abdomen. The diagnosis was chronic obstruction from matting of the small intestine, and the exploration was undertaken in the hope of removing the obstruction either by separation of adhesions or by enterectomy. On Feb. 17th Mr. Knaggs accordingly performed the following operation. A median incision, five inches long, was made, extending from an inch above the umbilicus. No layer with the usual characters of peritoneum was met with. A few adhesions between the parietes and the bowels were separated, and at the bottom of the wound were exposed loops of collapsed small intestine, closely agglutinated by adhesions, and containing a few scattered lumps of fæces. This collapsed intestine was thought to constitute part of the obstruction, and it was traced in one direction, its adhesion to the parietes and other portions of intestine being separated while doing so. Tracing some six or eight inches to the right showed the bowel to enter some structure at right angles—probably the cæcum—and so the tracing was reversed. After about another foot of intestine had been unravelled the finger was able to explore in the direction of the tumour, and felt what was probably distended intestine. Now, as the tracing went on, one or two knuckles of bowel were exposed, whose covering bore some resemblance to normal peritoneum, but still considerably altered by adhesions. It was evident that the portion of the bowel above the main obstruction was being approached, as these knuckles were full of fluid, though not greatly distended. But adhesions seemed universal, and the finger could not enter any definite cavity where the intestines were free from adhesions. A part of the bowel had now been reached which did not seem to have been much obstructed, and the intestine below it was beginning slowly to fill. The operator now began to divide the organised bands of lymph, which considerably contracted and distorted the collapsed coils. When this was done the coils were found to be decidedly fuller. The filling having taken place almost imperceptibly, and the operation having been very tedious and prolonged, it was deemed advisable, in the absence of any very clear indication, to bring it to a conclusion. The coils of intestine were returned into the abdominal cavity, a Keith's drainage-tube was placed in the recto-vesical pouch, and the incision closed. The dressings were so arranged that the tube could be emptied without interfering with the wound. The tube was nearly filled with boracic lotion and enclosed in other antiseptic dressings.

The patient was kept under the influence of morphia, given subcutaneously, and fed by nutrient suppositories and enemata. The temperature, which before the operation had run a normal course, was 102° on the night of the operation, but afterwards fell as low as 99°. The pulse varied from 120 to 140. The tube was dressed night and morning. At the first and every subsequent dressing a considerable quantity of purulent-looking discharge, having a decidedly fæcal odour, was taken away, the tube being on each occasion filled with boracic acid solution till it was perfectly clear. On Feb. 19th the material was a coagulated mass of lymph. On the 20th he had a copious motion, portions being formed; and during the night he was delirious and restless. On the 22nd, after another similar night, the bowels were again well opened, the motion being partly solid and partly fluid. The patient had become very exhausted, and died about 10.30 A.M., half an hour after the tube had been dressed.

The necropsy was made by Dr. L. P. Bevan, the abdomen only being examined. The incision was found to be imperfectly healed, and where unhealed it was unhealthy-looking. Fæcal matter filled the channel of the drainage-tube. On opening the wound the exposed coils were seen to be covered with greenish lymph, which was only superficial. The unravelled coils had formed fresh adhesions,

Digitized by Google

but they were distended, as was also the large intestine. By taking a point two inches above the umbilicus, and drawing imaginary lines from it to the lower ends of the costal arch, a diamond-shaped space was formed. Below this space the peritoneal cavity was practically obliterated; in the space itself there were numerous adhesions and bands, many of them of great strength, but the intestines here still maintained some peritoneal lustre, and were somewhat freely movable; they were dilated and thickened. Scattered throughout the abdominal cavity were a number of light-coloured caseating masses, some of a semi-pultaceous appearance, others more solid, and shining through a layer of peritoneum or false membrane. Several were found in the mesentery, others apparently in the midst of adhesions. One was placed in the anterior wall of the bladder, and another close to the pylorus on the greater curvature of the stomach. One of these masses, in the right lumbar region, had partly broken down into pus. The intestines were soft, and more than once gave way as the adhesions were being separated. The mucous surface of the intestine showed a small circular ulcer, with raised thickened edges, at the upper part of the ileum; and in the large intestine, close to the cæcum, was a group of some five or six perforations, with rounded edges, of varying size, the largest being almost as big as a shilling; one or two had a well-marked fenestrated appearance. Externally there were the remains of adhesions. The rest of the large intestine was healthy, except for the lymph external to it.

CASE 2.—E. R——, aged forty-three, married, no children. She dated her illness from March 7th, 1885, when she was seized with pain in the abdomen, and the bowels, which had hitherto acted with great regularity, ceased to act well. For ten days she felt poorly, with anorexia and abdominal pain, but no tenderness, and the bowels continued to act in an insufficient and irregular manner. Then she began to vomit, and the state of the bowels got worse and worse, in spite of aperients. She vomited daily, sometimes three or four times, and would bring up at intervals as much as a couple of pints of greenish fluid, after which she was considerably relieved. When seen by my father on May 7th, he found her much emaciated and exhausted, and unable to retain anything on the stomach. A hard swelling was perceptible towards the left side of the abdomen, extending from near the umbilicus to the pelvis. There was also retroversion of the uterus, but this seemed to have no connexion with the malady. She was placed upon liquid peptonised food, and a quarter of a grain of extract of belladonna, in form of pill, was ordered to be taken three times a day, belladonna ointment being applied to the abdomen.

On May 11th, 1885, she was admitted into the Huddersfield Infirmary, and the same plan was continued. No satisfactory progress was made. The bowels were never opened, except by enemata, and then only a few small scybala were passed. The vomiting continued as frequent and as copious as before admission, and the weakness and emaciation increased. An exploratory operation was therefore decided upon, and on June 20th, after consultation, Mr. Knaggs opened the abdomen in the median line by an incision three inches long below the umbilicus. Cautious exploration was then made with the finger, and a growth, or succession of growths, solid, and of a yellowish-white appearance, was felt and seen, evidently embedded in the mesentery, and extending downwards from about the position of the upper part of the left kidney to the left side of the pelvis. The peritoneum was studded with an infinite number of small tubercles.

The case seemed so hopeless that nothing further was attempted. The wound was closed, and it healed by first intention. There was no interruption to recovery. The results of the operation were singular and most unexpected. The patient vomited once within the next twenty-four hours, and for the last time. The bowels in a few days began to act with regularity, and improvement has been steady though slow. The patient when I last saw her (April 30th, 1886) was in a fair state of health, and able to get up and do light things about the house. She was better than she had been at any time since she left the infirmary, and she was continuing slowly to gain flesh both in the face and body. She every now and then suffered considerable pain from flatulence, and very frequently loud gurgling could be heard all over the room. She had only vomited two or three times since leaving the infirmary, and then the vomit was small, and due to something that had disagreed with her. The bowels acted twice daily, and the belladonna had been discontinued. No sign of disease existed about the lungs. When the intestines were not distended with gas there was a resonant tumour of variable size reaching from the umbilicus to the pubes, and evidently a mass of matted intestines. There was a movable lump as big as a walnut in the left iliac fossa, which had not varied in size, and was probably a large gland or a tubercular mass. At the fundus of the uterus was a craggy mass, which was close to a puckering and thickening of the mucous membrane of the rectum—probably healed ulceration.

Dr. Fagge in his article on intestinal obstruction,[1] after noticing that the primary cause of "contractions" was generally a chronic peritonitis, adds: "It might therefore be thought that ordinary strumous peritonitis would be likely to give rise to similar effects. Such an occurrence must however be rare, for I have looked up all the fatal cases in our modern post-mortem records without having met with any one in which symptoms of obstruction are stated to have existed." He then narrates a case, to which there was no history, to show that strumous peritonitis may cause narrowing of the intestine to such a degree as to lead to dilatation and thickening of the bowel above the narrowed part. Dr. Fagge has since recorded a case in which the obstruction was due to this cause.[2] And Mr. Maunder[3] records a case of "intestinal occlusion dependent upon tubercular disease of the intestines," where the tubercular deposit was entirely "in the substance of the peritoneal covering."

The two cases here recorded, which occurred in the practice of one surgeon within eight months of one another, were brought almost to death's door from the results of intestinal obstruction, and in neither was tubercular peritonitis suspected as the cause until the operation showed it to be so in the one and the post-mortem examination in the other. That tubercular peritonitis does not necessarily contra-indicate or add very seriously to the risks of an operation is sufficiently proved by the result of the second case. There is hardly room for doubt that the operation has already prolonged the patient's life many months, and her continued improvement in health without regular medicinal treatment may fairly raise the thought that the incision itself may have exercised a salutary effect upon the course of the disease. This case may be considered in connexion with Sir Spencer Wells' classical case in which recovery seemed to date from a sharp attack of peritonitis that came on after the incision. Another remarkable case has recently been recorded by Mr. Lawson Tait.[4]

In the first case no operation would have been attempted had the real state of affairs been foreseen, but appearances were thought to point to a localised lesion, and the circumstantial history of typhoid, doubtful as it may now appear when critically examined by the light of subsequent events, tended to obscure the diagnosis. I have very little doubt that what was looked upon as typhoid was really a subacute commencement of peritonitis or an exacerbation of one previously existing; yet it was quite within the bounds of possibility—perhaps even of probability—that the typhoid condition should have originated a localised peritonitis, and the feeling of resistance leading to the right groin was in favour of that suggestion; whilst the perforations that were actually found so close to where typhoid perforations might be expected is of interest when we consider the history of the case. The group of perforations at the beginning of the large intestine is interesting. Perforation of a tubercular ulcer is a rare but still an occasional occurrence, and an interesting case is recorded by Dr. Hale White.[5] The present case is remarkable from the fact that a group of ulcers perforated. Before the perforations occurred the intestines must have been glued together, and a fatal peritonitis prevented. How far they may have owed their origin to the dragging of an adherent coil upon their floors, already softened by the results of inflammation, it is impossible to say, but this does not seem an unreasonable explanation. It is curious that during the operation so little should have been seen of the remarkable conditions that were really present. Except one or two suspicious circumstances, which investigation failed to clear up, no inkling of the true cause was gathered. The collapsed coils exposed by the incision were not inconsistent with a

localised matting; but it was not till after death that by continued unravelling the true state of affairs became apparent.

In the second case, it is difficult to understand what led to the removal of the obstruction. It is possible, but unlikely, that some accidental touch during the operation may have done all that was necessary; but I incline rather to the belief that the relief was afforded in the same way as it is sometimes by an enterotomy. I think that the very careful feeding after the operation, assisted possibly by the vomiting, so reduced the distension above the obstruction and prevented its reaccumulation that the natural passage was restored, and that the action of the belladonna, with the subsequent careful diet, were sufficient to keep it open.

Huddersfield.

WHAT CONSTITUTES MALIGNANCY?[1]

BY HERBERT SNOW, M.D. LOND.,
SURGEON TO THE CANCER HOSPITAL.

THOUGH we are by no means yet in a position to solve the great mystery which surrounds this question, it appears to me that by discarding some useless lumber in the shape of pathological over-refinements, and by taking as general a view as possible of the whole subject, we may yet do much to narrow the problem, and to place ourselves face to face with it in its simplest form, shorn of all irrelevant matter—surely a by no means inconsiderable advantage towards its successful solution.

Taking first for our consideration the large class of malignant diseases denominated "alveolar carcinoma," with its principal subdivisions—scirrhus and encephaloid,—we are told that this is due to the proliferation of glandular epithelium in the meshes of a fibrous stroma, such stroma being firmly organised and most abundant in scirrhus, and comparatively scanty in encephaloid. Here the character of this stroma, and the emphasis laid upon it in pathological instruction, seem to me to obscure from our mental vision the essential and vital characteristics of the new growth. Some authorities consider it merely the original connective tissue of the part; others an entirely new formation; the most recent make an equally balanced compromise between the two. But I think that the prevailing impression in the medical mind is that this alveolar stroma is altogether a neoplasm, a characteristic and typical feature of the cancerous tumours. Let us now examine the correctness of this view, taking scirrhus as the most typical form of alveolar carcinoma and the female breast as its most ordinary seat. If we take a thin section from the normal breast, we see the bands of white fibrous tissue variously interlaced, so as to form irregular meshes; at intervals the acini of the gland lined by epithelium; here and there collections of adipose tissue. When the organ becomes affected by scirrhus, we find the epithelial cells of the acinus transgressing their boundaries, depositing themselves in the interstices of the normal connective tissue wherever they can gain a foothold, here proliferating abundantly and stretching the developing fibres, till in time these become atrophied or absorbed. In the last stage, as a rule, the cells greatly predominate; we then encounter only friable cell-masses, many of which have undergone caseous or fatty degeneration, with but a mere skeleton of the original fibrous tissues remaining.[2] On examining a section of the scirrhosed breast, we notice an acinar or alveolar distribution of the cell-masses, corresponding precisely to the normal arrangement of the fibrous bands, and in no way differing from it. When the section is through a plane parallel to the fibres, we find the cells apparently arranged in long thin rolls; when transverse, the cells appear grouped in larger or smaller irregularly roundish or oval clusters. Here and there some of the original acini of the gland remain, adding to the alveolar appearance.

But in order to find the most typical alveoli and the representation of scirrhous cancer most commonly given in pathological manuals, we must study the development of the cancer cells in fatty tissue. We here see these cells travelling from the affected part along the fibres of the reticulum; they locate themselves at the angles formed by the crossing of the different fibres and proliferate, crumpling up before them the fat-cell which each mesh contains. When the process is complete, the place of the fat-cell is wholly occupied by the malignant cells, and the original fibres of the reticulum remaining unaltered, the appearance presented under the microscope is that of large roundish acini. Throughout all this we utterly fail to find any development of new fibrous tissue. It cannot be denied that there may occasionally take place (as in other conditions of chronic irritative inflammation) some hypertrophic increase of fibrous tissue in the vicinity of a cancerous tumour; the skin of a cancerous breast often *seems* thickened, even to a long distance from the seat of disease. But this phenomenon is by no means constant, is of an accidental nature, and has nothing whatever to do with the alveolar characteristics of the neoplasm. The most careful examination of numerous cases has entirely failed to indicate to me that there is any increase of fibrous tissue whatever in ordinary cases of scirrhus, whether hypertrophic or of new formation. The gist of the whole process of development in scirrhous cancer of the breast appears simply to be that the cells of the acini, under the influence of some law at present very mysterious to us, proliferate abnormally, diffuse themselves through the adjoining tissues by the agency of lymph currents (probably also by their own amœboid movements), and grow vigorously wherever they can find room; but that their distribution depends strictly on the anatomical structure of the part, and proceeds on lines previously laid down.

I will pause here a moment to make one or two further remarks respecting the relationship of the white fibrous tissue to scirrhus, which we have just been considering; because I believe that many or most people look upon the characteristic hardness of a scirrhous tumour as due to the superabundance of such tissue in and around it, and perhaps at the first glance will not be able otherwise to account for the very marked induration which we almost always find. The fallacy of such an idea will, however, be obvious when we consider that a tumour composed wholly of white fibrous tissue has no such feature; still more so when we remember the soft pulpy character (in ordinary situations) of the growth we term "round-celled sarcoma" (which in abdominal organs I have seen not a whit more solid to the touch than condensed milk), and then reflect that this material, when enveloped by a rigidly resisting capsule, as in the case of the testicle, feels to us of stony hardness. A still more striking example is afforded by lympho-sarcomatous tumours, which, usually not particularly remarkable for their hardness to the touch, when growing under dense fascia in the lower part of the neck are commonly mistaken at first for an exostosis, then for osteoid cancer. The truth is, that the sensation to our hand of hardness occasioned ordinarily by scirrhus, and extraordinarily by the tumours just mentioned, results from the tension of cell-masses growing under or among the meshes of resisting non-elastic tissue. A similar explanation will account for the puckering of the skin, for the retraction of the nipple, and general tendency to shrinking and contraction in the adjoining tissues, most marked in the case of scirrhus, though by no means confined to this; the growing cell-masses haul on the fibres, somewhat in the same way as a sailor hauls on a rope.[3]

Next as to encephaloid cancer. We hear little of this nowadays. There is a fashion in pathology, as in most things else; and the present custom is to designate tumours which would formerly have been classed under this heading as "round-celled sarcoma." I venture to think that this is a great mistake; and that the latter term, implying as it does a connective tissue origin, is employed far too frequently at the present day. In the case of the female breast, I cannot but assign an *epithelial* origin to the tumours commonly termed "sarcoma," together with a certain degree of alveolar structure proportionate to the stage of the tumour and to the amount of fibrous tissue still remaining; and I therefore prefer for these the old and unfashionable term

[1] This paper constitutes part of a lecture introductory to the course delivered by the staff of the Cancer Hospital from January to March, 1886.

[2] This description, of course, does not refer to those exceptional chronic adatrophic cases in which the fibrous tissue is not eroded; though even here I should hesitate to call it hypertrophied.

[3] A familiar example of the enormous energy exerted by proliferating cell-masses—often in themselves soft, pulpy, and friable—must occur to all who have noticed the power with which colonies of young fungi elevate heavy slabs or stones overlying their bed; and we know how the algæ, growing on the lees of wine which has issued from a small leak in a cask, may eventually lift the whole cask up many inches.

Digitized by Google

"encephaloid."[4] These growths on section often remind one of pomegranate, the soft pulpy cell-masses being contained in coarse meshes of the connective tissue of the part, and their vascularity adds to the general resemblance. On inspecting a thin section of one of these, the brown bands of fibrous tissue will be seen in contrast with the dark-blue cell-masses. Under the microscope we find cells of pretty much the same character as the former; as a rule they are not quite so large or so well defined, but their growth appears to be far more exuberant. Instead of little detached knots of cells inserting themselves, as it were, painfully and with difficulty into the connective tissue meshes, we find huge masses; these are still contained in alveoli, only that the latter are now very large and coarse. The cell-masses at first keep within the bounds of the normal acinus of the gland—soon, however, transgressing this; they are evidently the results of proliferation of the epithelium appertaining to that acinus, and show no indications of any connective tissue origin.

The question now arises: If these two forms of cancer (scirrhous and encephaloid) both arise from the acinar epithelium, how is it that they are clinically so distinct—so that in the one case we find a tumour of stony hardness, in the other a growth comparatively soft, perhaps even fluctuating? The former is characterised by puckering and contraction, the latter by prominence and distension. I think we may find a plausible explanation of these peculiarities in the state of the white fibrous tissue of the individual patient. Those who have occasion to operate frequently on the female breast must have noticed, when proceeding to scoop out the contents of the axilla, the marked difference in the consistence of the normal tissues here situated—a difference by no means referable solely to age, but in great measure also plainly depending on natural habit of body: so that in one woman you may clean out the cavity with great ease; in another, not markedly distinguished from the former in age or general appearance, the fibrous tissues are exceedingly tough, and have to be divided by the knife or scissors. I would, then, refer the clinical and other differences between scirrhus and encephaloid cancer, as these affect the female breast, simply to differences in the resisting power of the white fibrous tissue in the individual who happens to suffer from the one or the other. In scirrhus, as a rule, the malignant cells force their way with difficulty, only gradually eroding their fibrous envelopes; in encephaloid, the cells prey, if I may so speak, on the surrounding fibrous tissue from the first, and there is no resistance, no pressure, no increase of tension, no feeling of hardness to the touch. I do not see how else to account for the facts, but I cannot venture, however, to offer the above hypothesis as more than provisional.

(To be concluded.)

[4] If carefully looked for, a typical scirrhous appearance may nearly always be found at some part of the section of these tumours, a point tending strongly to indicate an identical origin.

EPITHELIAL CANCER OF THE TONGUE LIP, AND UTERUS.

BY JOHN CLAY, M.D.,
PROFESSOR OF MIDWIFERY, QUEEN'S COLLEGE, BIRMINGHAM.

IT is now six years since I first communicated to THE LANCET (March, 1880) some observations, with illustrative cases, on the use of Chian Turpentine in the Treatment of Cancer. Much outspoken, not to say hostile, criticism of the remedy characterised the discussion which resulted from that communication. I have not troubled myself to enter upon this controversy, nor, with the space at my disposal, can I now venture to do so. I have been content to steadily pursue the treatment in the course of my own practice, and with such excellent results as to justify me in adhering to the statements I made in the paper above referred to. As the test of experience is the most conclusive reply that can be made to the criticisms and objections offered to my method of treatment, I now submit such evidence, in the form of brief notes on three cases of cancer, in different positions, each treated by Chian turpentine. I offer these, not as isolated examples, but as types of a number of successes obtained by similar treatment in cases alike as to their character and their situation. In the name of suffering humanity, I ask the medical profession to consider these cases without prejudice, and in the hope that the narration of them may lead to a more extensive and resolute trial of a remedy the high value of which I have tested and proved in my own practice.

CASE 1. *Epithelioma of the Tongue.*—On March 30th, 1885, I saw, in consultation with Mr. Bury of New Barnet, Mr. M—— of Shrewsbury, aged fifty-nine years, a gentleman retired from business. The medical gentleman in charge of the case informed me that the patient was suffering from epithelioma of the tongue, and that he had consulted two of the highest authorities in London, who had confirmed his diagnosis, and had pronounced the case to be unsuitable for operation. It was reported to me that one of the consultants confidentially expressed the opinion that the disease would probably prove fatal within two months. The disease was first noticed about four months previous to the above-named date. It commenced with soreness on the right side, at the junction of the root of the tongue with the floor of the mouth. There was some ulceration at this part, which was attributed to the irritation of a decayed tooth. The tooth was extracted, but the soreness and ulceration were not relieved, but gradually increased. The patient has never had syphilis. He has had caustics applied occasionally, and had taken sedatives to ease the pain. On examination, I found, in the situation above mentioned, an ulceration about the size of a sixpence, with a hardened and everted edge on the tongue side of it. There was a row of raised shot-like epithelial growths (not in a state of ulceration) proceeding from the ulcer on the lateral border of the tongue, and running forwards towards the tip for about three-quarters of an inch. The tissues around the ulceration and growths were thickened and hard from cancerous infiltration. There was an enlarged submaxillary gland about the size of a pullet's egg. The movements of the tongue were limited and painful. The patient was well nourished, but depressed and anxious. I gave an unfavourable prognosis, but thought it was a case in which Chian turpentine ought to be perseveringly tried, as that seemed to be the only alternative left to him. He was ordered the following mixture: eight ounces of Chian turpentine (Southall's) and two drachms of resorcin, two teaspoonfuls three times daily; and to have the ulcer and growths slightly painted on alternate days, respectively with chromic acid solution (ten grains to the ounce) and solution of perchloride of mercury (one grain to the ounce). On April 16th, 1885, Mr. Bury wrote to me thus: "There is no arrest of the glandular enlargement, which, if anything, is somewhat more marked. The ulcer in the tongue about as before. I presume we must not lose all heart because the remedies do not seem to have arrested the disease; possibly sufficient time has not elapsed since the commencement of the use of the medicines." On June 30th he again wrote to me, and in reference to this point stated that "about a week after your reply to me the enlargement of the glands began to disperse, and in about three weeks it was entirely gone. The ulcer of the tongue is, I believe, quite healed." I mention these facts, as it is a too common error on the part of medical men to imagine that the remedy is useless because its effects are not apparent in a few days. I did not see the patient again until July 10th, 1885, when I was surprised to find him looking so well. As I had heard nothing of him I feared that he had succumbed to the disease. On examination I found the enlarged gland had disappeared; the tongue could be moved freely and without pain; on the right side it looked and felt quite normal, as though it had never been affected. On the left side of the neck, however, I discovered an enlarged gland, and on the lateral border of the tongue on the same side I found an epithelial growth of the size of a hazel-nut in a sloughing condition. The remedies were ordered to be continued as before. I saw the patient about a month afterwards. The newly discovered growth had all but disappeared, and a month later I found the parts free from disease. The medicine was directed to be taken in diminished doses, and the local applications to be discontinued. I saw him in December of the same year, when he was quite well and proposed spending some weeks on the Continent. I quote the following remarks on the case from a letter from Mr. Bury, the medical gentleman already referred to: "You will be greatly pleased with the success of your remedies, which have restored to life, one may truly say, under God's blessing, one doomed to die in the course of a few months."

CASE 2. *Epithelioma of the Upper Lip.*—Mrs. W——, aged fifty-two years. General health good; has had four children, but no miscarriages; never had syphilis; menopause about eight years previously. She consulted me on October 20th, 1883, at the Queen's Hospital, ostensibly for a vaginal discharge, but really for a growth occupying nearly the whole of the upper lip and involving the lower portion of the left ala nasi. She had been under the care of Mr. W. Freer, who had advised its removal. It presented a fungating raised appearance, and was irregular in outline. The surrounding tissue was hard to the touch, and the cancerous infiltration extended some distance around the nodule. A small portion was excised by scissors, and examined by the resident physician and resident obstetric surgeon under the microscope, in the fresh state, and well-marked "epithelial nests" reported. On account of the occasional hæmorrhages, the growth was painted over once with perchloride of iron solution, and afterwards dressed with vaseline. The *simple* Chian turpentine mixture was ordered to be taken three times daily, in two-teaspoonful doses. The patient presented herself regularly every fortnight at the hospital, and at the end of ten weeks the mass had shrunk considerably, and had a black appearance; the infiltration had disappeared, and she was now free from pain. In the twelfth week the mass felt loose, but it was not interfered with. Thirteen weeks from the commencement of the treatment, on getting up in the morning, the patient found that the mass had separated during the night. The lip was free from hardness, and movable. There was a white cicatrix about the size of a shilling, and a slight notch in the margin of the lip. I saw her on August 16th, 1886; she was quite well, and there had been no recurrence of the disease.

CASE 3. *Epithelioma of the Os and Cervix Uteri.*—Mrs. W——, aged fifty-four years. Very feeble and emaciated, and cachexia well marked. Could not walk a hundred yards even with assistance. Has had very profuse watery and sanguineous uterine discharges for several weeks. Mr. L. Tait, who had seen her previously, had, she stated, pronounced the case to be uterine cancer, and incurable, and that she could not live a fortnight. On examining the uterus, a mass of epitheliomatous cancer, about the size of a hen's egg, occupied the upper part of the vagina, but believed to be limited to the uterus; it bled freely from the examination. I ordered the Chian turpentine mixture with resorcin, and directed her to use vinegar-and-water injections. At the end of seven weeks the hæmorrhage and leucorrhœal discharges had nearly ceased, and the patient could now walk more than a mile twice weekly to see me. The growth had almost disappeared. At the end of five months she had increased 15 lb. in weight. About the seventh month she had an attack of facial paralysis affecting the right side, which probably arose from cold. She recovered almost completely. Now (a year and a half from the commencement of the treatment) she can attend to her household duties as well as she could before her illness. The growth has cicatrised completely. There is a small nodule, which appears to be healthy, and represents the os and the cervix of the uterus.

Birmingham.

TROPICAL ABSCESS OF THE LIVER.

BY SURGEON A. TOMES,
INDIAN MEDICAL SERVICE.

(*Concluded from page 669.*)

WITH regard to the treatment, there are two drugs which are eminently useful in the presuppurative stage of hepatitis—ipecacuanha and chloride of ammonium. The use of the former, advocated by Professor Maclean, in the same large doses as for acute dysentery, has proved of the utmost value in reducing sthenic hepatitis of Europeans. I prefer the latter for natives, in doses of from fifteen to twenty grains, combined with quinine and hydrochloric acid. Experience having taught us the immense risks to life that attend the plan of non-interference when an abscess has formed, and knowing also that the prospect of a cure by operative treatment depends largely upon the stage at which it is undertaken, our utmost attention must be paid to the early detection of pus. So soon as there is any suspicion of suppuration the liver must be explored; there is no need to wait for the abscess to declare itself. It is now a routine practice among surgeons in India to explore the liver with a long fine needle or trocar. The instrument, which may be attached to an aspirator, is plunged into the organ towards the suspected seat, and even when no pus is found no evil result has ever been known to follow. On the contrary, the acute symptoms are generally relieved by the procedure. I have heard of practitioners who puncture not merely for an exploratory purpose, but as a curative measure, in acute hepatitis.

In advanced cases there may be no difficulty of diagnosis. There will be a large, tense, fluctuating swelling occupying the hypochondrium. Actual pointing is rare, and in all cases where there is any doubt the aspirator should first be employed to determine the presence and position of the abscess. Supposing pus to be detected, the rule is to evacuate. Thirty years ago, heavy as the mortality from unrelieved ulcer was known to be, surgeons hesitated to interfere. They preferred to wait in hopes of a cure by natural processes. Results of operation were most unfavourable, because it was undertaken too late, and because entrance of unpurified air produced septic decomposition. They never operated unless the abscess came to the surface and distinctly fluctuated. With earlier detection, improved instruments, and antiseptic precautions, operation is followed by a greater measure of success in modern times. Still, the circumstances attending the formation of an abscess in the liver are such that the proportion of recoveries will always be small. The disease is the outcome of a constitutional affection; there is a tendency to complication by bowel complaint and to multiplicity. Effect of climate can be met by removal to Europe. Multiplicity cannot usually be detected during life. One abscess may be successfully opened and drained, while another, a deeper one, bursts internally and destroys life.

In the absence of a sufficiently extensive and complete series of cases, where all results are given, the failures as well as the successes, it is impossible to estimate accurately what greater degree of success attends operative interference at the present time. It appears that formerly the mortality was little, if at all, lessened by operation. In the 81 cases collected by Dr. Waring (1832-52), the cures were 15, or 18·5 per cent., but he distinctly admitted that the proportion was much overstated, the cases having been in a great measure selected for report. As far as I have been able to make out from a study of 136 unselected cases operated on in recent times, the recovery rate is now about 22 per cent. Taking small series, the results are very variable. In one series of 9 operated on in a Calcutta hospital, 1 only was cured. In another series of 14, 8 were cured. Surgeon-Major (now Brigade-Surgeon) Curran[1] collected 24 cases, with 4 recoveries. Of the 8 cases in "Murchison's Clinical Lectures," 3 were cured. In my own, 20, all natives, the recoveries were 5, or 25 per cent.

The diagnosis of an abscess having been confirmed, there are two methods of dealing with it—the open and the close. The close consists in emptying the sac by a single or several aspirations at intervals, until it becomes obliterated. The open method means the establishment either by the knife, or by an ordinary trocar, of a permanent opening, and draining off the contents until that same end is attained. Formerly there was no choice; the open method was the only one available. When the aspirator was invented some sixteen years ago, it was hoped this would mark the commencement of a new era in the history of the treatment of liver abscess: difficulties would now be overcome, all risks avoided, and evacuation effected with certain success. These expectations, alas! have not been realised in full. As an instrument for diagnosis the aspirator has proved invaluable. But it is found that only a certain number (the smaller proportion) of abscesses suitable for operation can be cured by aspiration alone. Cases occur over and over again where the cavity speedily refills as soon as emptied, and the open has to be substituted for the close method. Aspiration, by causing centripetal tension on the walls, appears to favour the refilling of the cavity. At least two-thirds of all cases that have been cured by operation have been treated on the open method. In my opinion a cure should always be attempted by aspiration, for this method is the more agreeable to the patient, while the risks of septicism are avoided.

Moreover, it is far more rapid. If the case is capable of cure at all by the close method, it is cured promptly after one or two tappings, while the open is always a tedious business.

Abscesses of small or medium size, and limited by a distinct wall or membrane, also quiescent abscesses, are those most likely to be cured by aspiration. Cures have resulted after a single aspiration of as much as 16 oz., 30 oz., and in one remarkable case 112 oz. of pus. This last would be scarcely credible were it not for the established reputation of the author, Professor McConnell, of Calcutta. The operation may need repeating a second or even a third time, but when it is necessary to tap oftener than that, my experience is that the establishment of a permanent drain is called for. In operating by this method, it is a question whether the abscess should be completely emptied or not. I am in favour of partial evacuation in any but small collections, to aspirate slowly, and to desist as soon as the fluid runs with difficulty. The liver cannot so contract upon a large cavity as it is emptied as to effect its obliteration. A vacuum results, to fill which there is a rapid reaccumulation of fluid (pus, broken-down tissue, and exudation from the vessels). A guide as to the advisability of persevering in the close treatment in any case will be afforded by the character and quantity of the contents, and by the temperature range. If the contents are proved to have become of the uniform yellow character of laudable pus, that indicates the cessation of the breaking-down process and the formation of a limiting membrane. In aspirating, it is best to use the largest-sized trocar, because liver pus is apt to be so thick, tenacious, and shreddy. Having discovered its presence by the fine explorer, that may be left *in situ* as a guide. The larger trocar is then fitted and introduced along it, having first incised the skin with a scalpel to facilitate its entrance, and to avoid an unpleasant or even dangerous jerk. The operation is not painful, except at first, when the skin is perforated, but it is one that patients usually very much dread. On one occasion the patient suddenly flinched before the instrument even touched him, with the result of internal rupture and death. Since reading that account I have been in the habit of giving chloroform. Local anæsthesia by cocaine might answer. For establishing a free opening some prefer the knife, but a large trocar is usually employed. The skin having been incised, the trocar is boldly slid along the exploring needle (Sir J. Fayrer's grooved needles offer great advantages for this purpose) to the required extent. If no guide is used, the cessation of resistance will indicate that the cavity has been reached. It is advisable to leave the cannula *in situ* for a few days, to allow of adhesions forming, otherwise the organ may shift its position on its removal, when the reintroduction of a tube will be difficult and free escape of pus prevented. Subsequently a drainage-tube is substituted for the cannula, and its end received into a bunch of absorbent dressings. Post-mortem examinations show that adhesions do not always exist, though they are generally found. The risk of extravasation has, however, been exaggerated, and the tendency of modern surgeons is to disregard the point in determining the period for operation. Where no adhesions exist at the time of operation, if a tube be left in the wound, lymph is very soon thrown out around it, shutting it off from the pleural or peritoneal cavity through which it passes. It has been found completely isolated by the second day. The drainage-tube should not have lateral perforations throughout its length—granulations from the walls of the sinus in which it lies are apt to sprout into them and prevent its extension in the process of contraction of the cavity. One or two large holes near the end are all that is necessary.

Which is the best site for opening an abscess? As a general principle, the puncture is to be made where pus can be most readily reached, as indicated by fluctuation or by exploration. But whenever a choice is permitted, it is advisable to open *below* the ribs, for these reasons: 1. An opening in the intercostal space is apt to become obliterated on the collapse of the liver by the falling together of the ribs; this may necessitate excision of a portion of one or more to preserve patency of channel. 2. If a soft rubber tube be left in, it is liable to be compressed by the approximation of the ribs, and escape of pus will be interfered with. 3. If a silver cannula be left in, it may, by its irritating pressure, excite periostitis, and even necrosis.

When recovery has followed the spontaneous external bursting of an abscess, the opening is nearly always below the ribs, generally in the epigastrium, in the neighbourhood of the ensiform cartilage. When an abscess bursts through the thoracic wall recovery is rare; death is preceded by necrosis of ribs and sloughing of integument (Maclean). Thus nature clearly indicates the best route for evacuation. Statistics also show that better results attend operation below the ribs. Out of ten abscesses tapped between the ribs eight died and two recovered, or at the rate of 20 per cent.; out of twenty-two tapped below the ribs twelve died and ten recovered, or at the rate of 45·4 per cent. For aspiration the same rule does not apply. It is dangerous to aspirate towards the extreme upper and lower borders of the enlarged organ, for on removal of the trocar (the largest is used) there probably will be nothing to prevent extravasation of pus or blood. The liver contracts and alters its relation to the parietes in those directions. Extreme limits should be avoided, but there is little risk if aspiration is performed in the region where the organ is in constant contact with the chest wall, and there is no fear of necrosis after aspiration through an interspace.

It is scarcely necessary to say that the most stringent antiseptic precautions must be observed. It is impossible to prevent the entrance of air under the open method, but it can be rendered harmless by filtration through an antiseptic medium. In any case the accident is less dangerous where there is a free exit for its escape than where the cavity is sealed up. A large abscess will discharge an enormous quantity of matter, and the dressings rapidly get soaked, so that it is a difficult thing to keep the patient clean, and the decomposition of the discharges in the dressings is a great source of danger, especially in the tropics. With regard to washing out the cavity, as long as the pus keeps sweet this is unnecessary. Irrigation does not diminish the amount of discharge, but rather tends to increase it by its irritating effects on the walls.

I especially recommend for adoption the excellent method of dealing with abscess of the liver on the open method devised by Dr. Patrick Manson of Amoy.[2] By his plan the risks of extravasation of pus or blood where no adhesions exist, and of septic infection from decomposing discharges or entrance of foul air, are avoided; while at the same time the cavity is perfectly and constantly drained, and the patient maintained in a condition of comfort and cleanliness throughout. Having employed it, I can testify to its great value and convenience. The apparatus consists of a large trocar and cannula; a piece of drainage-tubing eight or ten inches long, of a diameter rather larger than that of the cannula; six feet of indiarubber tubing, half an inch bore, one end being fitted with a silver tube two inches long, fixed in the centre of an antiseptic pad; and a piece of waterproof sheeting. The calibre of this silver tube is such that the end of the drainage-tube can be easily and accurately fitted into it; the other end of the six-foot tubing is fastened within a small wide-mouthed phial placed in a large wide-mouthed jar. The jar, phial, and tube are filled with antiseptic solution, and the tube is clamped at its ends. The abscess is tapped with the trocar, and while pus is flowing the drainage-tube, previously stretched on a staff to reduce its calibre, by tying its distal end over a cap or with a piece of catgut, drawing in its proximal end and fastening it with string to the eye of the staff, is then slipped through the cannula to the full depth of the cavity. The cannula is withdrawn over the stretched tube; the tube is then released by cutting the string, and immediately springs to its full diameter, thus completely filling up the openings in the liver and parietes, and bridging over any interval that may exist between them. The free end of the drainage-tube is inserted into the connecting silver ferrule. A flannel binder is applied around the chest above and below the tubes and the pads and waterproof, to keep the apparatus in place. The clamps are removed from the long tubing, and its syphoning action set going. The contents of the abscess pass into the small phial, which is kept submerged in the solution in the jar, and thus acts as a trap. The jar is placed on the floor at the bedside, and is emptied and refilled from time to time as occasion requires. The length of the tube allows full play to the movements of the patient. After a day or two, it is found that the drainage-tube is no longer firmly held; it will have dilated the opening by its presence, and will lie loosely; any discharge that may now escape at its side will be caught up in the antiseptic dressings under the waterproof. By this

time a wall of lymph will have formed around it, shutting it off from the visceral cavity.

Whenever an abscess is being drained, it is important to remember the necessity of shortening the tube from time to time as the cavity contracts. I have known an abscess close in around an unshortened tube until at last the latter came to lie in a mere sinus of a length corresponding to the depth of the original cavity. The walls of the sinus continued to secrete pus, and this led to a false impression as to the progress made, until lateral exploration with a probe at once revealed the true state of affairs.

Shepherd's-bush.

ON RECURRING VENOUS THROMBOSIS FOLLOWING CHRONIC PYELITIS OF GONORRHŒAL ORIGIN.

BY H. FRENCH BANHAM, M.A., M.D.,
PHYSICIAN TO THE ROYAL BERKSHIRE HOSPITAL.
